## **Abstract**

Disclaimer: This is work in progress, I plan to add more material and/or change/reorganize the content.

In this monograph, I introduce the basic concepts of Online Learning through a modern view of Online Convex Optimization. Here, online learning refers to the framework of regret minimization under worst-case assumptions. I present first-order and second-order algorithms for online learning with convex losses, in Euclidean and non-Euclidean settings. All the algorithms are clearly presented as instantiation of Online Mirror Descent or Follow-The-Regularized-Leader and their variants. Particular attention is given to the issue of tuning the parameters of the algorithms and learning in unbounded domains, through adaptive and parameter-free online learning algorithms. Non-convex losses are dealt through convex surrogate losses and through randomization. The bandit setting is also briefly discussed, touching on the problem of adversarial and stochastic multi-armed bandits. These notes do not require prior knowledge of convex analysis and all the required mathematical tools are rigorously explained. Moreover, all the included proofs have been carefully chosen to be as simple and as short as possible.

I want to thank all the people that checked the proofs and reasonings in these notes. In particular, the students in my first class that mercilessly pointed out my mistakes, Nicolò Campolongo that found all the typos in my formulas, and Jake Abernethy for the brainstorming on presentation strategies. Other people that helped me with comments, feedback, references, and/or hunting typos (in alphabetical order): Andreas Argyriou, Param Kishor Budhraja, Nicolò Cesa-Bianchi, Keyi Chen, Mingyu Chen, Peiqing Chen, Gerardo Durán-Martín, Ryan D'Orazio, Alon Gonen, Peijia Guo, Daniel Hsu, Gergely Imreh, Andrew Jacobsen, Emmeran Johnson, Ji-Ha Kim, Andrew Christian Kroer, Kwang-Sung Jun, Michał Kempka, Pierre Laforgue, Wei-Cheng Lee, Chuang-Chieh Lin, Shashank Manjunath, David Martínez-Rubio, Aryan Mokhtari, Antoine Moulin, Gergely Neu, Ankit Pensia, Daniel Roy, Ludovic Schwartz, Alex Shtoff, Yanze Song, Luca Viano, Guanghui Wang, Yulian Wu, Jiujia Zhang, Peng Zhao, and Xingyu Zhou.

This material is based upon work that was supported by the National Science Foundation under grant no. 1925930 "Collaborative Research: TRIPODS Institute for Optimization and Learning".

A note on citations: it is customary in the computer science literature to only cite the journal version of a result that first appeared in a conference. The rationale is that the conference version is only a preliminary version, while the journal one is often more complete and sometimes more correct. In these notes, I will not use this custom. Instead, in the presence of the conference and journal version of the same paper, I will cite both. The reason is that I want to clearly delineate the history of the ideas, their first inventors, and the unavoidable rediscoveries. Hence, I need the exact year when some ideas were first proposed. Moreover, in some rare cases the authors changed from the conference to the journal version, so citing only the latter would erase the contribution of some key people from the history of Science.

# **Chapter 1**

# What is Online Learning?

Consider the following repeated game:

In each round  $t = 1, \ldots, T$ 

- An adversary chooses a real number in  $y_t \in [0, 1]$  and he keeps it secret;
- You try to guess the real number, choosing  $x_t \in [0, 1]$ ;
- The adversary's number is revealed and you pay the squared difference  $(x_t y_t)^2$ .

Basically, we want to guess a sequence of numbers as precisely as possible. To be a game, we now have to decide what is the "winning condition". Let's see what makes sense to consider as a winning condition.

First, let's make the game easier for the player. Let's assume that the adversary is drawing the numbers i.i.d. from some fixed distribution over [0,1]. However, he is still free to decide which distribution at the beginning of the game. If we knew the distribution, we could just predict each round the mean of the distribution and in expectation we would pay  $\sigma^2 T$ , where  $\sigma^2$  is the variance of the distribution. We cannot do better than that! However, given that we do not know the distribution, it is natural to benchmark our strategy with respect to the optimal one. That is, it is natural to measure the quantity

$$\mathbb{E}_Y \left[ \sum_{t=1}^T (x_t - Y)^2 \right] - \sigma^2 T, \tag{1.1}$$

or equivalently considering the average

$$\frac{1}{T}\mathbb{E}_Y\left[\sum_{t=1}^T (x_t - Y)^2\right] - \sigma^2. \tag{1.2}$$

Clearly these quantities are positive and they seem to be a good measure, because they are somehow normalized with respect to the "difficulty" of the numbers generated by the adversary, through the variance of the distribution. It is not the only possible choice to measure our "success", but for sure it is a reasonable one. It would make sense to consider a strategy "successful" if the difference in (1.1) grows sublinearly over time and, equivalently, if the difference in (1.2) goes to zero as the number of rounds T goes to infinity. That is, on average on the number of rounds, we would like our algorithm to be able to approach the optimal performance.

**Minimizing Regret.** Given that we have converged to what it seems a good measure of success of the algorithm, let's now rewrite (1.1) in an equivalent way

$$\mathbb{E}\left[\sum_{t=1}^{T} (x_t - Y)^2\right] - \min_{x \in [0,1]} \mathbb{E}\left[\sum_{t=1}^{T} (x - Y)^2\right].$$

Now, the last step: let's remove the assumption on how the data is generated, consider any arbitrary sequence of  $y_t$ , and keep using the same measure of success. Of course, we can remove the expectation because there is no stochasticity anymore. So, we get that we will win the game if

Regret<sub>T</sub> := 
$$\sum_{t=1}^{T} (x_t - y_t)^2 - \min_{x \in [0,1]} \sum_{t=1}^{T} (x - y_t)^2$$

grows sublinearly with T. The quantity above is called the *Regret*, because it measures how much the algorithm regrets for not sticking on all the rounds to the optimal choice in hindsight. We will denote it by  $\operatorname{Regret}_T$ . Our reasoning should provide sufficient justification for this metric, however in the following we will see that this also makes sense from both a convex optimization and machine learning point of view.

Note that in the stochastic case the optimal strategy is given by a single best prediction, so it was natural to compare against it. Instead, with arbitrary sequences it is not clear anymore that this is a good competitor. For example, we might consider a sequence of competitors instead of a single one. Indeed, it can be done, but the single competitor is still interesting in a variety of settings and simpler to explain. So, most of the time we will use a single competitor.

Let's now generalize the online game a bit more, considering that the algorithm outputs a vector in  $x_t$  in the valid set  $\mathcal{V} \subseteq \mathbb{R}^d$  and it pays a loss  $\ell_t : \mathcal{V} \to \mathbb{R}$  that measures how good was the prediction of the algorithm in each round. The set  $\mathcal{V}$  is called the *feasible set*. Also, let's consider an arbitrary predictor u in  $\mathcal{V} \subseteq \mathbb{R}^d$  and let's parameterize the regret with respect to it: Regret $_T(u)$ . So, to summarize, Online Learning is nothing else than designing and analyzing algorithms to minimize the Regret over a sequence of loss functions with respect to an arbitrary competitor  $u \in \mathcal{V} \subseteq \mathbb{R}^d$ :

$$\operatorname{Regret}_T(\boldsymbol{u}) := \sum_{t=1}^T \ell_t(\boldsymbol{x}_t) - \sum_{t=1}^T \ell_t(\boldsymbol{u}).$$

It is worth stressing that an online algorithm does not know u nor the value of the corresponding regret in order to guarantee an upper bound to the regret.

**Remark 1.1.** Strictly speaking, the regret is also a function of the losses  $\ell_1, \ldots, \ell_T$ . However, we will suppress this dependency for simplicity of notation.

This framework is pretty powerful, and it allows to reformulate a bunch of different problems in machine learning and optimization as similar games. More in general, with the regret framework we can analyze situations in which the data are not independent and identically distributed from a distribution, yet I would like to guarantee that the algorithm is "learning" something. For example, online learning can be used to analyze

- Prediction of clicks on banners on webpages;
- Routing on a network;
- Convergence to equilibrium of repeated games.

It can *also* be used to analyze stochastic algorithms, e.g., Stochastic Gradient Descent, but the adversarial nature of the analysis might give you suboptimal results. For example, it can be used to analyze momentum algorithms, but a naive treatment of the adversarial losses might might give a convergence guarantee that treats the momentum term as a vanishing disturbance that does not help the algorithm in any way.

Let's now go back to our number guessing game and let's try a strategy to win it. Of course, this is one of the simplest example of online learning, without a real application. Yet, going through it we will uncover most of the key ingredients in online learning algorithms and their analysis.

**A Winning Strategy.** Can we win the number guessing game? Note that we did not assume anything on how the adversary is deciding the numbers. In fact, the numbers can be generated in any way, even in an adaptive way based on our strategy. Indeed, they can be chosen *adversarially*, that is explicitly trying to make us lose the game. This is why we call the mechanism generating the number the *adversary*.

 $<sup>^1</sup>$ In same cases, we can make the game easier for the algorithm letting it choose the prediction from a set  $W \supset V$ .

The fact that the numbers are adversarially chosen means that we can immediately rule out any strategy based on any statistical modeling of the data. In fact, it cannot work because the moment we estimate something and act on our estimate, the adversary can immediately change the way he is generating the data, ruining us. So, we have to think about something else. Yet, many times online learning algorithms will look like classic ones from statistical estimation, even if they work for different reasons.

Now, let's try to design a strategy to make the regret provably sublinear in time, *regardless of how the adversary chooses the numbers*. The first thing to do is to take a look at the best strategy in hindsight, that is the argmin of the second term of the regret. It should be immediate to see that

$$x_T^* := \underset{x \in [0,1]}{\operatorname{argmin}} \sum_{t=1}^T (x - y_t)^2 = \frac{1}{T} \sum_{t=1}^T y_t.$$

Now, given that we do not know the future, for sure we cannot use  $x_T^{\star}$  as our guess in each round. However, we do know the past, so a reasonable strategy in each round could be to output the best number over the past. Why such strategy would work? For sure, the reason why it could work is not because we expect the future to be like the past, because it is not true! Instead, we want to leverage the fact that the optimal guess over time cannot change too much between rounds, so we can try to "track" it over time.

Hence, on each round t our strategy is to guess  $x_t = x_{t-1}^* = \frac{1}{t-1} \sum_{i=1}^{t-1} y_i$ . Such strategy is usually called *Follow-the-Leader* (FTL), because you are following what would have been the optimal thing to do on the past rounds (the Leader).

Let's now try to show that indeed this strategy will allow us to win the game. Given that this is a simple example, we will prove its regret guarantee using first principles. In the following, we will introduce and use very general proof methods. First, we will need a small lemma.

**Lemma 1.2.** Let  $V \subseteq \mathbb{R}^d$  and  $\ell_t : V \to \mathbb{R}$  an arbitrary sequence of loss functions. Denote by  $x_t^*$  a minimizer of the cumulative losses over the previous t rounds in V. Then, we have

$$\sum_{t=1}^{T} \ell_t(x_t^{\star}) \le \sum_{t=1}^{T} \ell_t(x_T^{\star}).$$

*Proof.* We prove it by induction over T. The base case is

$$\ell_1(x_1^{\star}) \le \ell_1(x_1^{\star}),$$

that is trivially true. Now, for  $T \ge 2$ , we assume that  $\sum_{t=1}^{T-1} \ell_t(x_t^{\star}) \le \sum_{t=1}^{T-1} \ell_t(x_{T-1}^{\star})$  is true and we must prove the stated inequality, that is

$$\sum_{t=1}^{T} \ell_t(x_t^{\star}) \le \sum_{t=1}^{T} \ell_t(x_T^{\star}) .$$

This inequality is equivalent to

$$\sum_{t=1}^{T-1} \ell_t(x_t^*) \le \sum_{t=1}^{T-1} \ell_t(x_T^*),\tag{1.3}$$

where we removed the last element of the sums because they are the same. Now observe that

$$\sum_{t=1}^{T-1} \ell_t(x_t^{\star}) \le \sum_{t=1}^{T-1} \ell_t(x_{T-1}^{\star}),$$

by induction hypothesis, and

$$\sum_{t=1}^{T-1} \ell_t(x_{T-1}^{\star}) \le \sum_{t=1}^{T-1} \ell_t(x_T^{\star})$$

because  $x_{T-1}^{\star}$  is a minimizer of the left hand side in  $\mathcal{V}$  and  $x_{T}^{\star} \in \mathcal{V}$ . Chaining these two inequalities, we have that (1.3) is true, and so the theorem is proven.

Basically, the above lemma quantifies the idea that knowing the future and being adaptive to it is typically better than not being adaptive to it.

With this lemma, we can now prove that the regret will grow sublinearly, in particular it will be at most *logarithmic* in time. Note that we will not prove that our strategy is minimax optimal, even if it is possible to show that the logarithmic dependency on time is unavoidable for this problem.

**Theorem 1.3.** Let  $y_t \in [0,1]$  for  $t=1,\ldots,T$  an arbitrary sequence of numbers. Let the algorithm's output  $x_t=x_{t-1}^{\star}:=\frac{1}{t-1}\sum_{i=1}^{t-1}y_i$ . Then, we have

Regret<sub>T</sub> = 
$$\sum_{t=1}^{T} (x_t - y_t)^2 - \min_{x \in [0,1]} \sum_{t=1}^{T} (x - y_t)^2 \le 4 + 4 \ln T$$
.

*Proof.* We use Lemma 1.2 to upper bound the regret:

$$\sum_{t=1}^{T} (x_t - y_t)^2 - \min_{x \in [0,1]} \sum_{t=1}^{T} (x - y_t)^2 = \sum_{t=1}^{T} (x_{t-1}^{\star} - y_t)^2 - \sum_{t=1}^{T} (x_T^{\star} - y_t)^2 \le \sum_{t=1}^{T} (x_{t-1}^{\star} - y_t)^2 - \sum_{t=1}^{T} (x_t^{\star} - y_t)^2.$$

Now, let's take a look at each difference in the sum in the last equation. We have that

$$(x_{t-1}^{\star} - y_t)^2 - (x_t^{\star} - y_t)^2 = (x_{t-1}^{\star})^2 - 2y_t x_{t-1}^{\star} - (x_t^{\star})^2 + 2y_t x_t^{\star}$$

$$= (x_{t-1}^{\star} + x_t^{\star} - 2y_t)(x_{t-1}^{\star} - x_t^{\star})$$

$$\leq |x_{t-1}^{\star} + x_t^{\star} - 2y_t| |x_{t-1}^{\star} - x_t^{\star}|$$

$$\leq 2|x_{t-1}^{\star} - x_t^{\star}|$$

$$= 2\left|\frac{1}{t-1}\sum_{i=1}^{t-1} y_i - \frac{1}{t}\sum_{i=1}^{t} y_i\right|$$

$$= 2\left|\left(\frac{1}{t-1} - \frac{1}{t}\right)\sum_{i=1}^{t-1} y_i - \frac{y_t}{t}\right|$$

$$\leq 2\left|\frac{1}{t(t-1)}\sum_{i=1}^{t-1} y_i\right| + \frac{2|y_t|}{t}$$

$$\leq \frac{2}{t} + \frac{2|y_t|}{t}$$

$$\leq \frac{4}{t}.$$

Hence, overall we have

$$\sum_{t=1}^{T} (x_t - y_t)^2 - \min_{x \in [0,1]} \sum_{t=1}^{T} (x - y_t)^2 \le 4 \sum_{t=1}^{T} \frac{1}{t}.$$

To upper bound the last sum, observe that we are trying to find an upper bound to the green area in Figure 1.1. As you can see from the picture, it can be upper bounded by 1 plus the integral of  $\frac{1}{t-1}$  from 2 to T+1. So, we have

$$\sum_{t=1}^{T} \frac{1}{t} \le 1 + \int_{2}^{T+1} \frac{1}{t-1} \, \mathrm{d}t = 1 + \ln T \,.$$

Let's write in words the steps of the proof: Lemma 1.2 allows us to upper bound the regret against the single best guess with the regret against the sequence  $x_1^{\star}, \ldots, x_T^{\star}$ . In turn, given that  $|x_t^{\star} - x_{t-1}^{\star}|$  goes to zero very fast, the total regret is sublinear in time.

There are a few things to stress on this strategy. The strategy does not have parameters to tune (e.g., learning rates, regularizers). Note that the presence of parameters does not make sense in online learning: We have only one

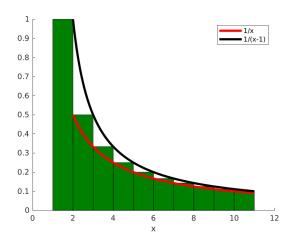

Figure 1.1: Upper bounding the sum with an integral.

stream of data and we cannot run our algorithm over it multiple times to select the best parameter! Also, it does not need to maintain a complete record of the past, but only a "summary" of it, through the running average. This gives a computationally efficient algorithm. When we design online learning algorithms, we will strive to achieve all these characteristics. Last thing that I want to stress is that the algorithm does not use gradients: Gradients are useful and we will use them a lot, but they do not constitute the entire world of online learning.

Before going on I want to remind you that, as seen above, this is different from the classic setting in statistical machine learning. So, for example, "overfitting" has absolutely no meaning here. Same for "generalization gap" and similar ideas linked to a training/testing scenario.

In the next chapters, we will introduce several algorithms for online optimization and one of them will be a strict generalization of the strategy we used in the example above.

## 1.1 History Bits

The concept of "regret" seems to have been proposed by Savage [1951], an exposition and review of the book by Wald [1950] on a foundation of statistical decision problems based on zero-sum two-person games. Savage [1951] introduces the idea of considering the difference between the utility of the best action in a given state and the utility incurred by any action under the same state. The proposed optimal strategy was the one minimizing such regret over the worst possible state. Savage [1951] called this concept "loss" and did not like the word "regret" because "that term seems to me charged with emotion and liable to lead to such misinterpretation as that the loss necessarily becomes known" [Savage, 1954, page 163]. The name of "regret" instead seems to have suggested in Milnor [1951].

However, Savage's definition is a modification of the one proposed by Wald [1950], who instead proposed to maximize just the utility, under the assumption that the utility of the best action for any state is 0. While minimizing the regret or the minimizing the negative utility under the assumption of Wald [1950] are mathematically equivalent, Savage [pages 169–170 1954] explains that Wald considered the regret formulation different from what he proposed, while Savage attributed to his idea "little or no originality".

Extending the definition of Savage [1951, 1954] to a sequence of games, Hannan [1957] designed a randomized algorithm for zero-sum repeated games with fixed loss matrix with a vanishing expected average regret. Hence, the concept of regret seems to originate from game theory, but strangely enough passing through the ideas of two mathematical statisticians.

Lemma 1.2 is due to Hannan [1957].

## **Exercises**

**Problem 1.1.** Extend the previous algorithm and analysis to the case when the adversary selects a vector  $\mathbf{y}_t \in \mathbb{R}^d$  such that  $\|\mathbf{y}_t\|_2 \leq 1$ , the algorithm guesses a vector  $\mathbf{x}_t \in \mathbb{R}^d$ , and the loss function is  $\|\mathbf{x}_t - \mathbf{y}_t\|_2^2$ . Show an upper bound to the regret logarithmic in T and that does not depend on d. Among the other things, you will probably need the Cauchy-Schwarz inequality:  $\langle \mathbf{x}, \mathbf{y} \rangle \leq \|\mathbf{x}\|_2 \|\mathbf{y}\|_2$ .

# **Chapter 2**

# **Online Subgradient Descent**

In this chapter, we will introduce the Online Subgradient Descent algorithm: a generic online algorithm to solve online problems with convex losses. First, we will introduce Online Gradient Descent for convex differentiable functions, then we will extend it to non-differentiable functions.

### 2.1 Online Learning with Convex Differentiable Losses

To summarize what we said in the first chapter, let's define an online learning as the following general game

- For t = 1, ..., T
  - Outputs  $oldsymbol{x}_t \in \mathcal{V} \subseteq \mathbb{R}^d$
  - Pay  $\ell_t(\boldsymbol{x}_t)$  for  $\ell_t: \mathcal{V} \to \mathbb{R}$
  - Receive some feedback on  $\ell_t$
- End for

The aim of this game is to minimize the regret with respect to any competitor  $u \in \mathcal{V}$ :

$$\operatorname{Regret}_T(\boldsymbol{u}) := \sum_{t=1}^T \ell_t(\boldsymbol{x}_t) - \sum_{t=1}^T \ell_t(\boldsymbol{u}).$$

We also said that the way the losses  $\ell_t$  are decided is adversarial. Now, without additional assumptions we cannot hope to solve this problem. Hence, we have to understand what are the *reasonable* assumptions we can make. Typically, we will try to restrict the choice of the loss functions in some way. This is considered reasonable because most of the time we have some say in deciding the set from which the loss functions are picked. So, for example, we will consider only *convex* loss functions. However, convexity might not be enough, so we might restrict the class a bit more to, for example, Lipschitz convex functions. On the other hand, assuming to know something about the future is not considered a reasonable assumption, because we very rarely have any control on the future. In general, the stronger the assumptions the better will be guarantee on the regret we can prove. The best algorithms we will see will guarantee a sublinear regret against the weakest assumption we can make, guaranteeing *at the same time* a smaller regret for *easy* adversaries.

It is also important to remember why minimizing the regret is a good objective: Given that we do not assume anything on how the adversary generates the loss functions, minimizing the regret is a good metric that takes into account the difficulty of the problem. If an online learning algorithm is able to guarantee a sublinear regret, it means that its performance on average will approach the performance of any fixed strategy. As said, we will see that in many situations if the adversary is "weak", for example it is a fixed stochastic distribution over the loss functions, being prepared for the worst-case scenario will not preclude us to get the best guarantee anyway.

For a while, we will focus on the case that  $\ell_t$  are convex, and this problem will be called **Online Convex Optimization** (OCO). Later, we will see how to *convexify* some specific non-convex online problems.

Remark 2.1. I will now introduce some math concepts. If you have a background in Convex Analysis, this will be easy stuff for you. On the other hand, if you never saw these things before they might look a bit scary. Let me tell you the right way to look at them: these are tools that will make our job easier. Without these tools, it would be basically impossible to design any online learning algorithm. And, no, it is not enough to test random algorithms on some machine learning dataset, because fixed datasets are not adversarial. Without a correct proof, you might not realize that your online algorithm fail on particular sequences of losses, as it happened to Adam [Reddi et al., 2018]. I promise you that once you understand the key mathematical concepts, online learning is actually easy.

#### 2.1.1 Convex Analysis Bits: Convexity

Figure 2.1: Non-convex (left) and convex (right) sets.

**Definition 2.2** (Convex Set).  $V \subset \mathbb{R}^d$  is **convex** if for any  $x, y \in V$  and any  $\lambda \in (0, 1)$ , we have  $\lambda x + (1 - \lambda)y \in V$ .

In words, this means that the set V has no holes, see Figure 2.1.

We will make use of **extended-real-valued functions**, that is function that take value in  $\mathbb{R} \cup \{-\infty, +\infty\}$ . For f an extended-real-valued function on  $\mathbb{R}^d$ , its **domain** is the set dom  $f = \{x \in \mathbb{R}^d : f(x) < +\infty\}$ .

Extended-real-valued functions allow us to easily consider constrained set and are a standard notation in Convex Optimization [see, e.g., Boyd and Vandenberghe, 2004]. For example, if I want the predictions of the algorithm  $x_t$  and the competitor u to be in a set  $\mathcal{V} \subset \mathbb{R}^d$ , I can just add  $i_{\mathcal{V}}(x)$  to all the losses, where  $i_{\mathcal{V}} : \mathbb{R}^d \to (-\infty, +\infty]$  is the **indicator function of the set**  $\mathcal{V}$  defined as

$$i_{\mathcal{V}}(\boldsymbol{x}) = \begin{cases} 0, & \boldsymbol{x} \in \mathcal{V}, \\ +\infty, & \text{otherwise.} \end{cases}$$

In this way, the only way for the algorithm and for the competitor to suffer finite loss is to predict inside the set V. Also, extended-real-valued functions will make the use of Fenchel conjugates more direct, see Section 6.4.1.

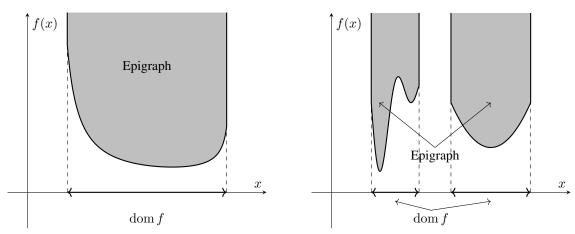

Figure 2.2: Convex (left) and nonconvex (right) functions.

Convex functions will be an essential ingredient in online learning.

**Definition 2.3** (Convex Function). Let  $f: \mathbb{R}^d \to [-\infty, +\infty]$ . f is **convex** if the epigraph of the function,  $\{(x, y) \in \mathbb{R}^{d+1} : y \geq f(x)\}$ , is convex.

We can see a visualization of this definition in Figure 2.2. Note that the definition implies that the domain of a convex function is convex. Also, observe that if  $f: \mathcal{V} \subseteq \mathbb{R}^d \to \mathbb{R}$  is convex,  $f+i_{\mathcal{V}}: \mathbb{R}^d \to (-\infty, +\infty]$  is also convex. Note that  $i_{\mathcal{V}}(x)$  is convex iff  $\mathcal{V}$  is convex, so each convex set is associated with a convex function.

The definition above gives rise to the following characterization for convex functions that do not assume the value  $-\infty$ .

**Theorem 2.4** ([Rockafellar, 1970, Theorem 4.1]). Let  $f : \mathbb{R}^d \to (-\infty, +\infty]$  and dom f is a convex set. Then f is convex iff, for any  $0 < \lambda < 1$ , we have

$$f(\lambda x + (1 - \lambda)y) \le \lambda f(x) + (1 - \lambda)f(y), \forall x, y \in \text{dom } f.$$

**Example 2.5.** The simplest example of convex functions are the affine functions:  $f(x) = \langle z, x \rangle + b$ .

**Example 2.6.** Norms are always convex, the proof is left as exercise.

How to recognize a convex function? In the most general case, you have to rely on its definition. However, most of the time we will recognize them as composed by operations that preserve the convexity. For example:

- f and g convex, then the linear combination with non-negative weights is also convex.
- The composition with an affine transformation preserves the convexity.
- Pointwise supremum of convex functions is convex.

The proofs are left as exercises.

A very important property of differentiable convex functions is that we can construct linear lower bound to the function.

**Theorem 2.7** ([Rockafellar, 1970, Theorem 25.1 and Corollary 25.1.1]). Suppose  $f: \mathbb{R}^d \to (-\infty, +\infty]$  a convex function and let  $x \in \text{int dom } f$ . If f is differentiable at x then

$$f(y) \ge f(x) + \langle \nabla f(x), y - x \rangle, \ \forall y \in \mathbb{R}^d$$
.

We will also use the first-order optimality condition for differentiable convex functions:

**Theorem 2.8.** Let  $\mathcal{V}$  be a convex non-empty set,  $\mathbf{x}^* \in \mathcal{V}$ , and f a convex function, differentiable over an open set that contains  $\mathcal{V}$ . Then,  $\mathbf{x}^* \in \operatorname{argmin}_{\mathbf{x} \in \mathcal{V}} f(\mathbf{x})$  iff  $\langle \nabla f(\mathbf{x}^*), \mathbf{y} - \mathbf{x}^* \rangle \geq 0$ ,  $\forall \mathbf{y} \in \mathcal{V}$ .

*Proof.* Let first assume that  $x^*$  satisfies  $\langle \nabla f(x^*), y - x^* \rangle \ge 0$ ,  $\forall y \in \mathcal{V}$ . Then, by Theorem 2.7, for any  $y \in \mathcal{V}$ , we have that

$$f(y) \ge f(x^*) + \langle \nabla f(x^*), y - x^* \rangle \ge f(x^*),$$

that is  $x^*$  is the minimizer of f over V.

Now, assume that  $\boldsymbol{x}^{\star}$  is the minimizer of f over  $\mathcal{V}$  and assume that there exists  $\boldsymbol{y} \in \mathcal{V}$  such that  $\langle \nabla f(\boldsymbol{x}^{\star}), \boldsymbol{y} - \boldsymbol{x}^{\star} \rangle < 0$ . Consider  $\boldsymbol{z}(\alpha) = \alpha \boldsymbol{y} + (1 - \alpha) \boldsymbol{x}^{\star}$  where  $\alpha \in (0,1)$ . Note that  $\boldsymbol{z}(\alpha) \in \mathcal{V}$  and denote by  $h(\alpha) = f(\boldsymbol{z}(\alpha))$ . We have that  $h'(0) = \langle \nabla f(\boldsymbol{x}^{\star}), \boldsymbol{y} - \boldsymbol{x}^{\star} \rangle < 0$ . Given that f is differentiable and so continuous, there exists  $\alpha^{\star}$  sufficiently small such that  $f(\boldsymbol{z}(\alpha^{\star})) < f(\boldsymbol{z}(0)) = f(\boldsymbol{x}^{\star})$  that contradicts that fact that  $\boldsymbol{x}^{\star}$  is the minimizer over  $\mathcal{V}$ .

In words, at the constrained minimum, the gradient makes an angle of  $90^{\circ}$  or less with all the feasible variations  $y-x^{\star}$ , hence we cannot minimize more the function moving inside  $\mathcal{V}$ . Moreover, if  $x^{\star} \in \text{int } V$ , by choosing  $\epsilon$  small enough such that  $y = x^{\star} - \epsilon \nabla f(x^{\star}) \in \mathcal{V}$ , we obtain that  $x^{\star}$  is a minimum iff  $\nabla f(x^{\star}) = \mathbf{0}$ .

Another critical property of convex functions is Jensen's inequality.

**Theorem 2.9.** Let  $f: \mathbb{R}^d \to (-\infty, +\infty]$  be a measurable convex function and x be an  $\mathbb{R}^d$ -valued random element on some probability space such that  $\mathbb{E}[x]$  exists and  $x \in \text{dom } f$  with probability 1. Then, we have

$$E[f(\boldsymbol{x})] > f(E[\boldsymbol{x}])$$
.

We can now see our first OCO algorithm in the case that the functions are convex and differentiable.

#### 2.1.2 Online Gradient Descent

In the first chapter, we saw a simple strategy to obtain a logarithmic regret in the guessing game. The strategy was to use the best over the past, that is the *Follow-the-Leader* strategy. In formulas,

$$x_t = \underset{x}{\operatorname{argmin}} \sum_{i=1}^{t-1} \ell_i(x),$$

and in the first round we can play any admissible point. One might wonder if this strategy always works, but the answer is negative!

**Example 2.10** (Failure of FTL). Let  $\mathcal{V} = [-1, 1]$  and consider the sequence of losses  $\ell_t(x) = z_t x$ , where

$$z_1 = -0.5,$$
  
 $z_t = 1, t = 2, 4, \dots$   
 $z_t = -1, t = 3, 5, \dots$ 

Then, apart from the first round where the prediction of FTL is arbitrary in [-1,1], the predictions of FTL will be  $x_t=1$  for t even and  $x_t=-1$  for t odd. The cumulative loss of the FTL algorithm after T rounds will therefore be  $T-1-\frac{x_1}{2}$  while the cumulative loss of the fixed solution u=0 is 0. Thus, the regret of FTL with respect to u=0 is  $T-1-\frac{x_1}{2} \geq T-\frac{3}{2}$ .

Hence, we will show an alternative strategy that guarantees sublinear regret for convex Lipschitz functions. Later, we will also prove that the dependency on T is optimal. The strategy is called Projected Online Gradient Descent, or just Online Gradient Descent, see Algorithm 2.1. It consists in updating the prediction of the algorithm at each time step moving in the negative direction of the gradient of the loss received and projecting back onto the feasible set. Some might see that this algorithm is similar to Stochastic Gradient Descent, but it is not the same thing: here the loss functions are different at each step and they are not drawn from a fixed distribution but adversarially chosen. We will later see that Online Gradient Descent can *also* be used as Stochastic Gradient Descent.

#### Algorithm 2.1 Projected Online Gradient Descent

**Require:** Non-empty closed convex set  $\mathcal{V} \subseteq \mathbb{R}^d$ ,  $x_1 \in \mathcal{V}$ ,  $\eta_1, \dots, \eta_T > 0$ 

- 1: for t = 1 to T do
- 2: Output  $\boldsymbol{x}_t \in \mathcal{V}$
- 3: Pay  $\ell_t(\boldsymbol{x}_t)$  for  $\ell_t: \mathcal{V} \to \mathbb{R}$  differentiable in an open set containing  $\mathcal{V}$
- 4: Set  $\boldsymbol{g}_t = \nabla \ell_t(\boldsymbol{x}_t)$
- 5:  $\boldsymbol{x}_{t+1} = \Pi_{\mathcal{V}}(\boldsymbol{x}_t \eta_t \boldsymbol{g}_t) = \operatorname{argmin}_{\boldsymbol{y} \in \mathcal{V}} \|\boldsymbol{x}_t \eta_t \boldsymbol{g}_t \boldsymbol{y}\|_2$
- 6: end for

First, we show the following two Lemmas. The first lemma proves that Euclidean projections always decrease the distance with points inside the set.

**Proposition 2.11.** Let  $x \in \mathbb{R}^d$  and  $y \in \mathcal{V}$ , where  $\mathcal{V} \subseteq \mathbb{R}^d$  is a non-empty closed convex set and define  $\Pi_{\mathcal{V}}(x) := \operatorname{argmin}_{y \in \mathcal{V}} \|x - y\|_2$ . Then,  $\|\Pi_{\mathcal{V}}(x) - y\|_2 \le \|x - y\|_2$ .

*Proof.* First of all, observe that  $\operatorname{argmin}_{\boldsymbol{y} \in \mathcal{V}} \|\boldsymbol{x} - \boldsymbol{y}\|_2 = \operatorname{argmin}_{\boldsymbol{y} \in \mathcal{V}} \frac{1}{2} \|\boldsymbol{x} - \boldsymbol{y}\|_2^2$ . So, from the optimality condition of Theorem 2.8 on the function  $f(\boldsymbol{y}) = \frac{1}{2} \|\boldsymbol{x} - \boldsymbol{y}\|_2^2$ , we obtain

$$\langle \Pi_{\mathcal{V}}(\boldsymbol{x}) - \boldsymbol{x}, \boldsymbol{y} - \Pi_{\mathcal{V}}(\boldsymbol{x}) \rangle \geq 0$$
.

Therefore,

$$\|\boldsymbol{y} - \boldsymbol{x}\|_{2}^{2} = \|\boldsymbol{y} - \Pi_{\mathcal{V}}(\boldsymbol{x}) + \Pi_{\mathcal{V}}(\boldsymbol{x}) - \boldsymbol{x}\|_{2}^{2}$$

$$= \|\boldsymbol{y} - \Pi_{\mathcal{V}}(\boldsymbol{x})\|_{2}^{2} + 2\langle \boldsymbol{y} - \Pi_{\mathcal{V}}(\boldsymbol{x}), \Pi_{\mathcal{V}}(\boldsymbol{x}) - \boldsymbol{x} \rangle + \|\Pi_{\mathcal{V}}(\boldsymbol{x}) - \boldsymbol{x}\|_{2}^{2}$$

$$\geq \|\boldsymbol{y} - \Pi_{\mathcal{V}}(\boldsymbol{x})\|_{2}^{2}.$$

The next lemma upper bounds the regret in one iteration of the algorithm.

**Lemma 2.12.** Let  $V \subseteq \mathbb{R}^d$  a non-empty closed convex set and  $\ell_t : V \to \mathbb{R}$  a convex function differentiable in an open set that contains V. Set  $g_t = \nabla \ell_t(x_t)$ . Then,  $\forall u \in V$ , the following inequality holds

$$\eta_t(\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) \le \eta_t\langle \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{u}\rangle \le \frac{1}{2}\|\boldsymbol{x}_t - \boldsymbol{u}\|_2^2 - \frac{1}{2}\|\boldsymbol{x}_{t+1} - \boldsymbol{u}\|_2^2 + \frac{\eta_t^2}{2}\|\boldsymbol{g}_t\|_2^2$$
.

*Proof.* From Proposition 2.11 and Theorem 2.7, we have that

$$\|\boldsymbol{x}_{t+1} - \boldsymbol{u}\|_{2}^{2} - \|\boldsymbol{x}_{t} - \boldsymbol{u}\|_{2}^{2} \leq \|\boldsymbol{x}_{t} - \eta_{t}\boldsymbol{g}_{t} - \boldsymbol{u}\|_{2}^{2} - \|\boldsymbol{x}_{t} - \boldsymbol{u}\|_{2}^{2}$$

$$= -2\eta_{t}\langle\boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{u}\rangle + \eta_{t}^{2}\|\boldsymbol{g}_{t}\|_{2}^{2}$$

$$\leq -2\eta_{t}(\ell_{t}(\boldsymbol{x}_{t}) - \ell_{t}(\boldsymbol{u})) + \eta_{t}^{2}\|\boldsymbol{g}_{t}\|_{2}^{2}.$$

Reordering, we have the stated bound.

We can prove the following regret guarantee.

**Theorem 2.13.** Let  $V \subseteq \mathbb{R}^d$  a non-empty closed convex set with diameter D, i.e.,  $\max_{\boldsymbol{x},\boldsymbol{y}\in\mathcal{V}}\|\boldsymbol{x}-\boldsymbol{y}\|_2 \leq D$ . Let  $\ell_1,\cdots,\ell_T$  an arbitrary sequence of convex functions  $\ell_t:V\to\mathbb{R}$  differentiable in open sets containing V. Pick any  $\boldsymbol{x}_1\in\mathcal{V}$  and assume  $\eta_{t+1}\leq\eta_t,\ t=1,\ldots,T$ . Then,  $\forall \boldsymbol{u}\in\mathcal{V}$ , the following regret bound holds

$$\sum_{t=1}^{T} (\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) \leq \frac{D^2}{2\eta_T} + \sum_{t=1}^{T} \frac{\eta_t}{2} \|\boldsymbol{g}_t\|_2^2 - \frac{1}{2\eta_T} \|\boldsymbol{x}_{T+1} - \boldsymbol{u}\|_2^2.$$

Moreover, if  $\eta_t$  is constant, i.e.,  $\eta_t = \eta \ \forall t = 1, \dots, T$ , we have

$$\sum_{t=1}^T (\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) \leq \frac{\|\boldsymbol{u} - \boldsymbol{x}_1\|_2^2}{2\eta} + \frac{\eta}{2} \sum_{t=1}^T \|\boldsymbol{g}_t\|_2^2 - \frac{1}{2\eta} \|\boldsymbol{x}_{T+1} - \boldsymbol{u}\|_2^2.$$

*Proof.* Dividing the inequality in Lemma 2.12 by  $\eta_t$  and summing over  $t = 1, \dots, T$ , we have

$$\begin{split} \sum_{t=1}^{T} (\ell_{t}(\boldsymbol{x}_{t}) - \ell_{t}(\boldsymbol{u})) &\leq \sum_{t=1}^{T} \left( \frac{1}{2\eta_{t}} \|\boldsymbol{x}_{t} - \boldsymbol{u}\|_{2}^{2} - \frac{1}{2\eta_{t}} \|\boldsymbol{x}_{t+1} - \boldsymbol{u}\|_{2}^{2} \right) + \sum_{t=1}^{T} \frac{\eta_{t}}{2} \|\boldsymbol{g}_{t}\|_{2}^{2} \\ &= \frac{1}{2\eta_{1}} \|\boldsymbol{x}_{1} - \boldsymbol{u}\|_{2}^{2} - \frac{1}{2\eta_{T}} \|\boldsymbol{x}_{T+1} - \boldsymbol{u}\|_{2}^{2} + \sum_{t=1}^{T-1} \left( \frac{1}{2\eta_{t+1}} - \frac{1}{2\eta_{t}} \right) \|\boldsymbol{x}_{t+1} - \boldsymbol{u}\|_{2}^{2} + \sum_{t=1}^{T} \frac{\eta_{t}}{2} \|\boldsymbol{g}_{t}\|_{2}^{2} \\ &\leq \frac{1}{2\eta_{1}} D^{2} + D^{2} \sum_{t=1}^{T-1} \left( \frac{1}{2\eta_{t+1}} - \frac{1}{2\eta_{t}} \right) + \sum_{t=1}^{T} \frac{\eta_{t}}{2} \|\boldsymbol{g}_{t}\|_{2}^{2} - \frac{1}{2\eta_{T}} \|\boldsymbol{x}_{T+1} - \boldsymbol{u}\|_{2}^{2} \\ &= \frac{1}{2\eta_{1}} D^{2} + D^{2} \left( \frac{1}{2\eta_{T}} - \frac{1}{2\eta_{1}} \right) + \sum_{t=1}^{T} \frac{\eta_{t}}{2} \|\boldsymbol{g}_{t}\|_{2}^{2} - \frac{1}{2\eta_{T}} \|\boldsymbol{x}_{T+1} - \boldsymbol{u}\|_{2}^{2} \\ &= \frac{D^{2}}{2\eta_{T}} + \sum_{t=1}^{T} \frac{\eta_{t}}{2} \|\boldsymbol{g}_{t}\|_{2}^{2} - \frac{1}{2\eta_{T}} \|\boldsymbol{x}_{T+1} - \boldsymbol{u}\|_{2}^{2}. \end{split}$$

In the same way, when the  $\eta_t$  is constant, we have

$$\begin{split} \sum_{t=1}^{T} (\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) &\leq \sum_{t=1}^{T} \left( \frac{1}{2\eta} \| \boldsymbol{x}_t - \boldsymbol{u} \|_2^2 - \frac{1}{2\eta} \| \boldsymbol{x}_{t+1} - \boldsymbol{u} \|_2^2 \right) + \frac{\eta}{2} \sum_{t=1}^{T} \| \boldsymbol{g}_t \|_2^2 \\ &= \frac{1}{2\eta} \| \boldsymbol{x}_1 - \boldsymbol{u} \|_2^2 - \frac{1}{2\eta} \| \boldsymbol{x}_{T+1} - \boldsymbol{u} \|_2^2 + \frac{\eta}{2} \sum_{t=1}^{T} \| \boldsymbol{g}_t \|_2^2 . \end{split}$$

We can immediately observe a few things.

- The terms  $\|g_t\|_2^2$  are due to the fact that we output  $x_t$  before knowing the loss  $\ell_t$ . Indeed, these terms become non-positive if we were allowed to observe  $\ell_t$  before producing  $x_t$ , see Section 12.6.
- In the case of constant  $\eta$ , the first term in the regret depends on our *initial condition*, that is how far is  $x_1$  from the competitor u.
- The last term in both bounds is non-positive, so it is usually discarded. Yet, some advanced proofs require it, so it is good to be aware of it.
- If we want to use time-varying learning rates, you need a bounded domain  $\mathcal{V}$  for the proof to work. However, this assumption is false in most of the machine learning applications. However, in the stochastic setting you can still use a time-varying learning rate in SGD with an unbounded domain if you use a non-uniform averaging. We will see this in Chapter 3.
- Another important observation is that the regret bound helps us choosing the learning rates  $\eta_t$ . Indeed, it is the only guideline we have. Any other choice that is not justified by a regret analysis it is not justified at all.

As we said, the presence of parameters like the learning rates make no sense in online learning. So, we have to decide a strategy to set them. A simple choice is to find the constant learning rate that minimizes the bounds for a fixed number of iterations. We have to consider the expression

$$rac{\|m{u} - m{x}_1\|_2^2}{2\eta} + rac{\eta}{2} \sum_{t=1}^T \|m{g}_t\|_2^2$$

and minimize with respect to  $\eta$ . It is easy to see that the optimal  $\eta$  is  $\frac{\|u-x_1\|_2}{\sqrt{\sum_{t=1}^T \|g_t\|_2^2}}$ , that would give the regret bound

$$\|m{u} - m{x}_1\|_2 \sqrt{\sum_{t=1}^T \|m{g}_t\|_2^2}$$
 .

However, we have a problem: in order to use this stepsize, we should know all the future gradients and the distance between the optimal solution and the initial point! This is clearly impossible: Remember that the adversary can choose the sequence of functions. Hence, it can observe your choice of learning rates and decide the sequence so that your learning rate is now the wrong one!

Indeed, it turns out that this kind of rate is completely impossible because it is ruled out by a lower bound. Yet, we will see that it is indeed possible to achieve very similar rates using *adaptive* (Section 4.2) and *parameter-free* algorithms (Chapter 10). For the moment, we can observe that we might be happy to minimize a loose upper bound. In particular, assume that the norm of the gradients is bounded by L, that is  $\|g_t\|_2 \le L$ . Also, assuming a bounded diameter, we can upper bound  $\|u - x_1\|_2$  by D. Hence, we have

$$\eta^{\star} = \underset{\eta}{\operatorname{argmin}} \ \frac{D^2}{2\eta} + \frac{\eta L^2 T}{2} = \frac{D}{L\sqrt{T}},$$

that gives a regret bound of

$$DL\sqrt{T}$$
 . (2.1)

So, indeed the regret is sublinear in time.

**Remark 2.14.** Sometimes people justify the Lipschitz assumption by arguing that a convex function is Lipschitz on any bounded subset of its domain, but in reality this is false. For example, the convex loss  $f(x) = -\sqrt{x}$  defined in  $[0,\infty)$  is not Lipschitz on any bounded set [0,a], where a>0. The actual result is more subtle: for example, one can show that any convex function is Lipschitz on closed bounded sets that are contained in the domain of the gradient. However, one has to be careful even with this statement. Again, the convex loss  $f(x) = -\sqrt{x}$  has Lipschitz constant equal to  $\frac{1}{2\sqrt{\epsilon}}$  on any interval  $[\epsilon, a]$ , where  $0 < \epsilon < a$ . Hence, the Lipschitz constant can be made arbitrarily large by minimal changes of the feasible set.

**Example 2.15.** Consider the guessing game of the first chapter, we can solve easily it with Online Gradient Descent. Indeed, we just need to calculate the gradients, prove that they are bounded, and find a way to calculate the projection of a real number in [0,1] So,  $\ell'_t(x) = 2(x-y_t)$ , that is bounded for  $x,y_t \in [0,1]$ . The projection on [0,1] is just  $\Pi_{[0,1]}(x) = \min(\max(x,0),1)$ . With the optimal learning rate, the resulting regret would be  $\mathcal{O}(\sqrt{T})$ , that is worse than the one we found in the first chapter.

**Example 2.16.** Let's consider an example of the online convex optimization setting. Consider the problem of predicting at day t the opening price of a stock based on a linear combination of the opening prices of the past d days, represented by a vector  $\mathbf{z}_t \in \mathbb{R}^d$ . So, our prediction at time t will be  $\langle \mathbf{z}_t, \mathbf{x}_t \rangle$  and the feasible set is  $\mathcal{V} = \mathbb{R}^d$ . Once we make our prediction, we receive the true opening price  $y_t$  and we pay the Huber loss, a convex loss function robust to outliers, on the difference between our prediction and the opening price:

$$\ell_t(\boldsymbol{x}) = \begin{cases} \frac{1}{2} (\langle \boldsymbol{z}_t, \boldsymbol{x} \rangle - y_t)^2, & \text{for } |\langle \boldsymbol{z}_t, \boldsymbol{x} \rangle - y_t| \leq \delta, \\ \delta(|\langle \boldsymbol{z}_t, \boldsymbol{x} \rangle - y_t| - \frac{1}{2}\delta), & \text{otherwise.} \end{cases}$$

We can use OGD for this problem, we just need to calculate the gradients:

$$\nabla \ell_t(\boldsymbol{x}) = \begin{cases} (\langle \boldsymbol{z}_t, \boldsymbol{x} \rangle - y_t) \boldsymbol{z}_t, & \textit{for } |\langle \boldsymbol{z}_t, \boldsymbol{x} \rangle - y_t| \leq \delta, \\ \delta \text{sign}(\langle \boldsymbol{z}_t, \boldsymbol{x} \rangle - y_t) \boldsymbol{z}_t, & \textit{otherwise}. \end{cases}$$

Assuming that  $|y_t|$  and  $||z_t||$  are bounded, we also have that these losses are Lipschitz, satisfying the assumptions of Theorem 2.13. Hence, I can run OGD and obtain that on average the performance of the algorithm will approach the performance of the a posteriori best linear predictor.

In the next Section, we will see how to remove the differentiability assumption through the use of *subgradients*.

### 2.2 Online Subgradient Descent

In the previous section, we have introduced Projected Online Gradient Descent. However, the differentiability assumption for the  $\ell_t$  is quite strong. What happens when the losses are convex but not differentiable? For example  $\ell_t(x) = |x-10|$ . Note that this situation is more common than one would think. For example, the hinge loss,  $\ell_t(\boldsymbol{w}) = \max(1-y\langle \boldsymbol{w}, \boldsymbol{x}\rangle, 0)$ , and the ReLU activation function used in neural networks,  $\ell_t(x) = \max(x,0)$ , are not differentiable. It turns out that we can just use Online Gradient Descent, substituting the *subgradients* to the gradients. For this, we need some more convex analysis!

#### 2.2.1 Convex Analysis Bits: Subgradients

First, we need a technical definition.

**Definition 2.17** (Proper Function). *If a function f is nowhere*  $-\infty$  *and finite somewhere, then f is called proper.* 

In this book, we are mainly interested in convex proper functions, that basically better conform to our intuition of what a convex function looks like.

**Example 2.18.** The indicator function of a set  $\mathcal{V} \subset \mathbb{R}^d$  is proper iff  $\mathcal{V}$  is non-empty.

Let's first define formally what is a subgradient.

**Definition 2.19** (Subgradient). For a proper function  $f : \mathbb{R}^d \to (-\infty, +\infty]$ , we define a subgradient of f in  $x \in \mathbb{R}^d$  as a vector  $g \in \mathbb{R}^d$  that satisfies

$$f(y) \ge f(x) + \langle g, y - x \rangle, \ \forall y \in \mathbb{R}^d$$
.

Basically, a subgradient of f in x is any vector g that allows us to construct a linear lower bound to f. Note that the subgradient is not unique, so we denote the *set* of subgradients of f in x by  $\partial f(x)$ , called **subdifferential of** f at f

Observe that if f is proper and convex, then  $\partial f(x)$  is empty for  $x \notin \text{dom } f$ , because the inequality cannot be satisfied when  $f(x) = +\infty$ . Also, the domain of  $\partial f$ , denoted by  $\text{dom } \partial f$ , is the set of all  $x \in \mathbb{R}^d$  such that  $\partial f(x)$  is nonempty; it is a subset of dom f. A proper convex function f is always subdifferentiable in int dom f [Rockafellar, 1970, Theorem 23.4].

Note that we did not assume the function f to be convex in the definition of a subgradient. However, the following theorem tells us that if we have subgradients everywhere, then the function must be convex.

**Theorem 2.20.** Let  $f: V \to \mathbb{R}$ , where  $V \subseteq \mathbb{R}^d$  is convex. If  $\partial f(x) \neq \{\}$  for all  $x \in V$ , then f is convex.

*Proof.* For any  $x_1, x_2 \in V$  and for any  $\lambda \in [0, 1]$ , consider  $y = \lambda x_1 + (1 - \lambda)x_2 \in V$  and  $g \in \partial f(y)$ . Then, we have

$$f(x_1) \ge f(y) + \langle g, x_1 - y \rangle = f(y) + (1 - \lambda)\langle g, x_1 - x_2 \rangle,$$
  
$$f(x_2) \ge f(y) + \langle g, x_2 - y \rangle = f(y) + \lambda\langle g, x_2 - x_1 \rangle.$$

Multiplying the first inequality by  $\lambda$  and the second one by  $1-\lambda$  and adding them together, we have

$$\lambda f(\boldsymbol{x}_1) + (1 - \lambda)f(\boldsymbol{x}_2) \ge f(\boldsymbol{y}) = f(\lambda \boldsymbol{x}_1 + (1 - \lambda)\boldsymbol{x}_2),$$

that implies the convexity of f in V.

The unique subgradient of a differentiable function is just the gradient, as quantified in the next Theorem.

**Theorem 2.21** ([Rockafellar, 1970, Theorem 25.1]). *If the function*  $f : \mathbb{R}^d \to [-\infty, +\infty]$  *is convex and finite in*  $\boldsymbol{x}$ , *it is differentiable in*  $\boldsymbol{x}$  *iff the subdifferential is composed by a unique element, that turns out to be*  $\nabla f(\boldsymbol{x})$ .

Also, we can also calculate subgradients of sum of functions.

**Theorem 2.22.** Let  $f_1, \ldots, f_m$  be proper functions on  $\mathbb{R}^d$ , and  $f = f_1 + \cdots + f_m$ . Then,  $\partial f(\mathbf{x}) \supseteq \partial f_1(\mathbf{x}) + \cdots + \partial f_m(\mathbf{x}), \forall \mathbf{x}$ . Moreover, if  $f_1, \ldots, f_m$  are also convex, closed, and dom  $f_m \cap \bigcap_{i=1}^{m-1} \operatorname{int} \operatorname{dom} f_i \neq \{\}$ , then actually  $\partial f(\mathbf{x}) = \partial f_1(\mathbf{x}) + \cdots + \partial f_m(\mathbf{x}), \forall \mathbf{x}$ .

*Proof.* For any z, define  $g_i \in \partial f_i(z)$  for  $i = 1, \dots, m$ . From the definition of subgradient, we have

$$f(oldsymbol{x}) = \sum_{i=1}^m f_i(oldsymbol{x}) \geq \sum_{i=1}^m (f_i(oldsymbol{z}) + \left\langle oldsymbol{g}_i, oldsymbol{x} - oldsymbol{z} 
ight
angle) = f(oldsymbol{z}) + \left\langle \sum_{i=1}^m oldsymbol{g}_i, oldsymbol{x} - oldsymbol{z} 
ight
angle \ .$$

Hence,  $\sum_{i=1}^{m} g_i \in \partial f(z)$ .

For the second statement, see Bauschke and Combettes [2011, Corollary 16.39].

**Example 2.23.** Let f(x) = |x|, then the subdifferential set  $\partial f(x)$  is

$$\partial f(x) = \begin{cases} \{1\}, & x > 0, \\ [-1, 1], & x = 0, \\ \{-1\}, & x < 0. \end{cases}$$

**Example 2.24.** Let's calculate the subgradient of the indicator function for a non-empty convex set  $V \subset \mathbb{R}^d$ . By definition,  $g \in \partial i_V(x)$  if

$$i_{\mathcal{V}}(\boldsymbol{y}) \geq i_{\mathcal{V}}(\boldsymbol{x}) + \langle \boldsymbol{g}, \boldsymbol{y} - \boldsymbol{x} \rangle, \ \forall \boldsymbol{y} \in \mathbb{R}^d$$
.

This condition implies that  $\mathbf{x} \in \mathcal{V}$  and  $0 \ge \langle \mathbf{g}, \mathbf{y} - \mathbf{x} \rangle, \forall \mathbf{y} \in \mathcal{V}$  (because for  $\mathbf{y} \notin V$  the inequality is always verified). The set of all  $\mathbf{g}$  that satisfies the above inequality is called the **normal cone to**  $\mathcal{V}$  **at**  $\mathbf{x}$  and it is denoted by  $N_{\mathcal{V}}(\mathbf{x})$ . Note that the normal cone for any  $\mathbf{x} \in \text{int } \mathcal{V} = \{\mathbf{0}\}$  (Hint: take  $\mathbf{y} = \mathbf{x} + \epsilon \mathbf{g}$ ). For example, for  $\mathcal{V} = \{\mathbf{x} \in \mathbb{R}^d : \|\mathbf{x}\|_2 \le 1\}$ ,  $N_{\mathcal{V}}(\mathbf{x}) = \{\alpha \mathbf{x} | \alpha \ge 0\}$  for all  $\mathbf{x} : \|\mathbf{x}\|_2 = 1$ .

Another useful theorem is to calculate the subdifferential of the pointwise maximum of convex functions.

**Theorem 2.25** ([Bauschke and Combettes, 2011, Theorem 18.5]). Let  $(f_i)_{i\in I}$  be a finite set of convex functions from  $\mathbb{R}^d$  to  $(-\infty, +\infty]$  and suppose  $\mathbf{x} \in \bigcap_{i\in I} \text{dom } f_i$  and  $f_i$  continuous at  $\mathbf{x}$ . Set  $F = \max_{i\in I} f_i$  and let  $A(\mathbf{x}) = \{i \in I | f_i(\mathbf{x}) = F(\mathbf{x})\}$  the set of the active functions. Then

$$\partial F(\boldsymbol{x}) = \operatorname{conv} \bigcup_{i \in A(\boldsymbol{x})} \partial f_i(\boldsymbol{x}),$$

where conv is the convex hull.

**Example 2.26** (Subgradients of the Hinge loss). Consider the loss  $\ell(x) = \max(1 - \langle z, x \rangle, 0)$  for  $z \in \mathbb{R}^d$ . The subdifferential set is

$$\partial \ell(\boldsymbol{x}) = egin{cases} \{ oldsymbol{0} \}, & 1 - \langle \boldsymbol{z}, \boldsymbol{x} 
angle < 0 \ \{ -lpha oldsymbol{z} | lpha \in [0, 1] \}, & 1 - \langle oldsymbol{z}, oldsymbol{x} 
angle = 0 \ \{ -oldsymbol{z} \}, & otherwise \end{cases}$$

Finally, we can show a result on the subgradient of affine transformations.

**Theorem 2.27.** Let  $f : \mathbb{R}^d \to (\infty, +\infty]$  proper. Define h(x) = f(Ax + b), where  $A \in \mathbb{R}^{m \times d}$  and  $b \in \mathbb{R}^m$ . Then, we have  $A^{\top} \partial f(Ax + b) \subseteq \partial h(x)$ .

*Proof.* For any  $g \in \partial f(Ax + b)$ , we want to show that  $A^{\top}g$  is a subgradient of h in x. From the definition of subgradient, for all  $y \in \mathbb{R}^d$  we have

$$h(\mathbf{x}) = f(\mathbf{A}\mathbf{y} + \mathbf{b}) \ge f(\mathbf{A}\mathbf{x} + \mathbf{b}) + \langle \mathbf{g}, \mathbf{A}\mathbf{y} + \mathbf{b} - (\mathbf{A}\mathbf{x} + \mathbf{b}) \rangle$$
  
=  $h(\mathbf{y}) + \langle \mathbf{A}^{\mathsf{T}}\mathbf{g}, \mathbf{y} - \mathbf{x} \rangle$ ,

that implies our stated result.

**Definition 2.28** (Lipschitz Function). Let  $f: \mathbb{R}^d \to (-\infty, +\infty]$  is L-Lipschitz over a set  $\mathcal{V}$  w.r.t a norm  $\|\cdot\|$  if  $|f(x) - f(y)| \le L \|x - y\|, \ \forall x, y \in \mathcal{V}$ .

We also have this handy result that upper bounds the norm of subgradients of convex Lipschitz functions.

**Theorem 2.29.** Let  $f: \mathbb{R}^d \to (-\infty, +\infty]$  proper. Then, f is L-Lipschitz in int dom f w.r.t. the  $L_2$  norm iff for all  $x \in \text{int dom } f$  and  $q \in \partial f(x)$  we have  $||q||_2 < L$ .

*Proof.* Assume f L-Lipschitz, then  $|f(x) - f(y)| \le L||x - y||_2$ ,  $\forall x, y \in \text{int dom } f$ . For  $\epsilon > 0$  small enough  $y = x + \epsilon \frac{g}{||g||_2} \in \text{int dom } f$ , then

$$L\epsilon = L\|\mathbf{x} - \mathbf{y}\|_2 \ge |f(\mathbf{y}) - f(\mathbf{x})| \ge f(\mathbf{y}) - f(\mathbf{x}) \ge \langle \mathbf{g}, \mathbf{y} - \mathbf{x} \rangle = \epsilon \|\mathbf{g}\|_2$$

that implies that  $\|\boldsymbol{g}\|_2 \leq L$ .

For the other implication, the definition of subgradient and Cauchy-Schwarz inequalities gives us

$$f(x) - f(y) \le ||g||_2 ||x - y||_2 \le L||x - y||_2$$

for any  $x, y \in \operatorname{int} \operatorname{dom} f$ . Taking  $g \in \partial f(y)$ , we also get

$$f(\boldsymbol{y}) - f(\boldsymbol{x}) \le L \|\boldsymbol{x} - \boldsymbol{y}\|_2,$$

that completes the proof.

Finally, let's dispel the common misconception that a convex function must be differentiable on its domain except possibly at countably many points. For example, consider the convex function  $f: \mathbb{R}^2 \to \mathbb{R}$  defined as  $f(x) = |x_1|$  that is not differentiable on the line segment between  $\mathbf{v} = (0,0)$  and  $\mathbf{w} = (0,1)$ .

#### 2.2.2 Analysis with Subgradients

As I promised you, with the proper mathematical tools, analyzing online algorithms becomes easy. Indeed, switching from gradient to subgradient comes for free! In fact, our analysis of OGD with differentiable losses holds as is using subgradients instead of gradients. The reason is that the only property of the gradients that we used in the proof of Theorem 2.13 was that

$$\ell_t(\boldsymbol{x}) - \ell_t(\boldsymbol{u}) \le \langle \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{u} \rangle,$$

where  $g_t = \nabla \ell_t(x_t)$ . However, the exact same property holds when  $g_t \in \partial \ell_t(x_t)$ . So, we can state the Online Subgradient descent algorithm in the following way, where the only difference is line 4.

#### Algorithm 2.2 Projected Online Subgradient Descent

**Require:** Non-empty closed convex set  $\mathcal{V} \subseteq \mathbb{R}^d$ ,  $x_1 \in \mathcal{V}$ ,  $\eta_1, \dots, \eta_T > 0$ 

- 1: for t = 1 to T do
- 2: Output  $x_t \in \mathcal{V}$
- 3: Pay  $\ell_t(\boldsymbol{x}_t)$  for an  $\ell_t: \mathcal{V} \to \mathbb{R}$  subdifferentiable in  $\mathcal{V}$
- 4: Set  $\boldsymbol{g}_t \in \partial \ell_t(\boldsymbol{x}_t)$
- 5:  $\boldsymbol{x}_{t+1} = \Pi_{\mathcal{V}}(\boldsymbol{x}_t \eta_t \boldsymbol{g}_t) = \operatorname{argmin}_{\boldsymbol{y} \in \mathcal{V}} \|\boldsymbol{x}_t \eta_t \boldsymbol{g}_t \boldsymbol{y}\|_2$
- 6: end for

Also, the regret bounds we proved hold as well, just changing differentiability with subdifferentiability and gradients with subgradients. In particular, we have the following Lemma.

**Lemma 2.30.** Let  $V \subseteq \mathbb{R}^d$  be a non-empty closed convex set and  $\ell_t : V \to \mathbb{R}$  a convex function subdifferentiable in V. Set  $g_t \in \partial \ell_t(\mathbf{x}_t)$ . Then,  $\forall \mathbf{u} \in V$ , the following inequality holds

$$\eta_t(\ell_t(m{x}_t) - \ell_t(m{u})) \le \eta_t\langle m{g}_t, m{x}_t - m{u} \rangle \le \frac{1}{2} \|m{x}_t - m{u}\|_2^2 - \frac{1}{2} \|m{x}_{t+1} - m{u}\|_2^2 + \frac{\eta_t^2}{2} \|m{g}_t\|_2^2 \ .$$

**Example 2.31.** Consider again the guessing game of the first class, but now change the loss function to the absolute loss of the difference:  $\ell_t(x) = |x - y_t|$ . Now we will need to use Online Subgradient Descent, because the functions are non-differentiable. We can easily see that

$$\partial \ell_t(x) = \begin{cases} \{1\}, & x > y_t \\ [-1, 1], & x = y_t \\ \{-1\}, & x < y_t \end{cases}.$$

Again, running Online Subgradient Descent with the optimal learning rate on this problem will give us immediately a regret of  $\mathcal{O}(\sqrt{T})$ , without having to design a specific strategy for it.

#### 2.3 From Convex Losses to Linear Losses

Let's take a deeper look at this step

$$\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u}) \leq \langle \boldsymbol{q}_t, \boldsymbol{x}_t - \boldsymbol{u} \rangle, \ \forall \boldsymbol{u} \in \mathbb{R}^d$$
.

Summing over time, we have

$$\sum_{t=1}^T (\ell_t(oldsymbol{x}_t) - \ell_t(oldsymbol{u})) \leq \sum_{t=1}^T \langle oldsymbol{g}_t, oldsymbol{x}_t - oldsymbol{u} 
angle, \ orall oldsymbol{u} \in \mathbb{R}^d$$
 .

Now, define the linear (and convex) losses  $\tilde{\ell}_t(x) := \langle g_t, x \rangle$ , so we have

$$\sum_{t=1}^T (\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) \leq \sum_{t=1}^T (\tilde{\ell}_t(\boldsymbol{x}_t) - \tilde{\ell}_t(\boldsymbol{u})) .$$

This is more powerful that what it seems: We upper bounded the regret with respect to the convex losses  $\ell_t$  with a regret with respect to another sequence of linear losses. This is important because it implies that we can build online algorithms that deal only with linear losses, and through the reduction above they can be seamlessly used as OCO algorithms! Note that this not imply that this reduction is always optimal, as we saw in Example 2.15. But, it allows us to easily construct optimal OCO algorithms in many interesting cases.

So, we will often consider just the problem of minimizing the linear regret

$$\operatorname{Regret}_T(\boldsymbol{u}) = \sum_{t=1}^T \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle - \sum_{t=1}^T \langle \boldsymbol{g}_t, \boldsymbol{u} \rangle, \ \forall \boldsymbol{u} \in \mathcal{V} \subseteq \mathbb{R}^d.$$

This problem is called **Online Linear Optimization** (OLO).

### 2.4 History Bits

Shor [1964] first introduced the subgradient descent method using a related concept of generalized gradients for non-differentiable functions. Instead, the concept of subgradients and the possibility to build a calculus for them appear for the first time in Rockafellar [1963]. The Projected Online Gradient Descent with time-varying learning rate and the name "Online Convex Optimization" was introduced by Zinkevich [2003], but the OCO framework was introduced earlier by Gordon [1999a,b].

Before the online convex optimization framework, the online learning community focused on specific losses and mostly linear predictors, see Cesa-Bianchi and Lugosi [2006]. Moreover, the concept of subgradient is also a recent addition to the online learning literature, and the earlier papers using subgradients of loss functions seem to be Zhang [2004], Shalev-Shwartz and Singer [2006b]. However, subgradients were implicitly used in previous analyses too, see for example Cesa-Bianchi [1999, Theorem 4].

It is impossible not to notice that the literature on OCO is heavily biased on the use of bounded domains. Yet, there are very few practical applications of OCO where the domain is bounded. Moreover, as shown in Theorem 2.13, it is possible to have a sublinear regret even in unbounded domains. I speculate that the insistence on using bounded domains is due to two main reasons: the less general definition of regret (derived from the setting of learning with experts (Section 6.8)) as

$$\sum_{t=1}^{T} \ell_t(\boldsymbol{x}_t) - \min_{\boldsymbol{u} \in V} \sum_{t=1}^{T} \ell_t(\boldsymbol{u})$$

that requires the existence of the minimizer of the sum of the losses and the fact that OMD with time-varying learning rates has a vacuous regret upper bound on unbounded domains. However, we now know that both these two issues can easily be fixed i) by defining the regret with respect to arbitrary competitors and ii) by using different algorithms, for example, FTRL. Indeed, even in offline optimization the existence of the minimizer is not required to guarantee that the suboptimality gap goes to zero, as we will see in Example 3.2. So, it is probably time for the community to stop using the crutch of bounded domains just to avoid technical difficulties.

#### 2.5 Exercises

**Problem 2.1.** Prove that  $\sum_{t=1}^{T} \frac{1}{\sqrt{t}} \leq 2\sqrt{T} - 1$ .

**Problem 2.2.** Using the inequality in the previous exercise, prove that a learning rate  $\eta_t \propto \frac{1}{\sqrt{t}}$  gives rise to a regret only a constant multiplicative factor worse than the one in (2.1).

**Problem 2.3.** Calculate the subdifferential set of the  $\epsilon$ -insensitive loss:  $f(x) = \max(|x - y| - \epsilon, 0)$ . It is a loss used in regression problems where we do not want to penalize predictions x within  $\pm \epsilon$  of the correct value y.

**Problem 2.4.** Using the definition of subgradient, find the subdifferential set of  $f(x) = ||x||_2$ ,  $x \in \mathbb{R}^d$ .

**Problem 2.5.** Consider Projected Online Subgradient Descent for the Example 2.10 on the failure of Follow-the-Leader: Can we use it on that problem? Would it guarantee sublinear regret? How the behaviour of the algorithm would differ from FTL?

# **Chapter 3**

# **Online-to-Batch Conversion**

In this chapter, we take a break from online learning theory and see some application of online learning to other domains. For example, we may wonder what is the connection between online learning and stochastic optimization. Given that Projected Online (Sub)Gradient Descent looks basically the same as Projected Stochastic (Sub)Gradient Descent, they must have something in common. Indeed, we can show that, for example, we can reduce stochastic optimization of convex functions to OCO. Let's see how.

### 3.1 From Online Learning to Stochastic Optimization

**Theorem 3.1.** Let V be a non-empty closed convex set of  $\mathbb{R}^d$ ,  $F(x) = \mathbb{E}[f(x, \xi)]$  where the expectation is w.r.t.  $\xi$  drawn from a distribution  $\rho$  over some vector space  $\mathcal{X}$ , and  $f: V \times \mathcal{X} \to \mathbb{R}$  is convex and subdifferentiable in the first argument in V. Draw T samples  $\xi_1, \ldots, \xi_T$  i.i.d. from  $\rho$  and construct the sequence of losses  $\ell_t(x) = \alpha_t f(x, \xi_t)$ , where  $\alpha_t > 0$  are deterministic. Run any OCO algorithm over the losses  $\ell_t$ , to construct the sequence of predictions  $x_1, \ldots, x_{T+1}$ . Then, we have

$$\mathbb{E}\left[F\left(\frac{1}{\sum_{t=1}^{T} \alpha_t} \sum_{t=1}^{T} \alpha_t \boldsymbol{x}_t\right)\right] \leq F(\boldsymbol{u}) + \frac{\mathbb{E}[\operatorname{Regret}_T(\boldsymbol{u})]}{\sum_{t=1}^{T} \alpha_t}, \ \forall \boldsymbol{u} \in \mathcal{V},$$

where the expectation is with respect to  $\boldsymbol{\xi}_1, \dots, \boldsymbol{\xi}_T$ .

Proof. We first show that

$$\mathbb{E}\left[\sum_{t=1}^{T} \alpha_t F(\boldsymbol{x}_t)\right] = \mathbb{E}\left[\sum_{t=1}^{T} \ell_t(\boldsymbol{x}_t)\right]. \tag{3.1}$$

In fact, from the linearity of the expectation we have

$$\mathbb{E}\left[\sum_{t=1}^T \ell_t(\boldsymbol{x}_t)\right] = \sum_{t=1}^T \mathbb{E}\left[\ell_t(\boldsymbol{x}_t)\right] \ .$$

Then, from the law of total expectation, we have

$$\begin{split} \mathbb{E}_{\boldsymbol{\xi}_{1},\dots,\boldsymbol{\xi}_{T}}\left[\ell_{t}(\boldsymbol{x}_{t})\right] &= \mathbb{E}_{\boldsymbol{\xi}_{1},\dots,\boldsymbol{\xi}_{t-1}}\left[\mathbb{E}_{\boldsymbol{\xi}_{t},\dots,\boldsymbol{\xi}_{T}}\left[\ell_{t}(\boldsymbol{x}_{t})|\boldsymbol{\xi}_{1},\dots,\boldsymbol{\xi}_{t-1}\right]\right] \\ &= \mathbb{E}_{\boldsymbol{\xi}_{1},\dots,\boldsymbol{\xi}_{t-1}}\left[\mathbb{E}_{\boldsymbol{\xi}_{t},\dots,\boldsymbol{\xi}_{T}}\left[\alpha_{t}f(\boldsymbol{x}_{t},\boldsymbol{\xi}_{t})|\boldsymbol{\xi}_{1},\dots,\boldsymbol{\xi}_{t-1}\right]\right] \\ &= \mathbb{E}_{\boldsymbol{\xi}_{1},\dots,\boldsymbol{\xi}_{t-1}}\left[\mathbb{E}_{\boldsymbol{\xi}_{t}}\left[\alpha_{t}f(\boldsymbol{x}_{t},\boldsymbol{\xi}_{t})|\boldsymbol{\xi}_{1},\dots,\boldsymbol{\xi}_{t-1}\right]\right] \\ &= \mathbb{E}_{\boldsymbol{\xi}_{t},\dots,\boldsymbol{\xi}_{T}}\left[\alpha_{t}F(\boldsymbol{x}_{t})\right], \end{split}$$

where we used the fact that  $x_t$  depends only on  $\xi_1, \dots, \xi_{t-1}$ . Hence, (3.1) is proved.

It remains only to use Jensen's inequality, using the fact that F is convex, to have

$$F\left(\frac{1}{\sum_{t=1}^{T} \alpha_t} \sum_{t=1}^{T} \alpha_t \boldsymbol{x}_t\right) \leq \frac{1}{\sum_{t=1}^{T} \alpha_t} \sum_{t=1}^{T} \alpha_t F(\boldsymbol{x}_t).$$

Dividing the regret by  $\sum_{t=1}^{T} \alpha_t$  and using the above inequalities gives the stated theorem.

Let's see now some applications of this result: Let's see how to use the above theorem to transform Online Subgradient Descent in Stochastic Subgradient Descent to minimize the training error of a classifier.

**Example 3.2.** Consider a problem of binary classification, with inputs  $z_i \in \mathbb{R}^d$  and outputs  $y_i \in \{-1,1\}$ . The loss function is the hinge loss:  $f(x,(z,y)) = \max(1-y\langle z,x\rangle,0)$ . Suppose that you want to minimize the training error over a training set of N samples,  $\{(z_i,y_i)\}_{i=1}^N$ . Also, assume the maximum  $L_2$  norm of the samples is R. That is, we want to minimize

$$\min_{\boldsymbol{x}} F(\boldsymbol{x}) := \frac{1}{N} \sum_{i=1}^{N} \max(1 - y_i \langle \boldsymbol{z}_i, \boldsymbol{x} \rangle, 0) .$$

Run the reduction described in Theorem 3.1 for T iterations using OGD. In each iteration, construct  $\ell_t(\boldsymbol{x}) = \max(1 - y_t \langle \boldsymbol{z}_t, \boldsymbol{x} \rangle, 0)$  sampling a training point uniformly at random from 1 to N. Set  $\boldsymbol{x}_1 = \boldsymbol{0}$  and  $\eta = \frac{1}{R\sqrt{T}}$ . We have that

$$\mathbb{E}\left[F\left(\frac{1}{T}\sum_{t=1}^{T}\boldsymbol{x}_{t}\right)\right] - F(\boldsymbol{x}^{\star}) \leq R\frac{\|\boldsymbol{x}^{\star}\|_{2}^{2} + 1}{2\sqrt{T}},$$

for all  $x^* \in \operatorname{argmin}_x F(x)$ . In words, we used an OCO algorithm to stochastically optimize a function, transforming the regret guarantee into a convergence rate guarantee.

In this last example, we have to use a constant learning rate to be able to minimize the training error over the entire space  $\mathbb{R}^d$ . In the next one, we will see a different approach, that allows to *implicitly* use a varying learning rate without the need of a bounded feasible set.

**Example 3.3.** Consider the same setting of the previous example, and let's change the way in which we construct the online losses. Now use  $\ell_t(\boldsymbol{x}) = \frac{1}{R_3 \sqrt{t}} \max(1 - y_t \langle \boldsymbol{z}_t, \boldsymbol{x} \rangle, 0)$  and step size  $\eta = 1$ . Hence, we have

$$\mathbb{E}\left[F\left(\frac{1}{\sum_{t=1}^{T} \frac{1}{\sqrt{t}}} \sum_{t=1}^{T} \frac{1}{\sqrt{t}} \boldsymbol{x}_{t}\right)\right] - F(\boldsymbol{x}^{\star}) \leq \frac{\|\boldsymbol{x}^{\star}\|_{2}^{2}}{2\sum_{t=1}^{T} \frac{1}{R\sqrt{t}}} + \frac{1}{2\sum_{t=1}^{T} \frac{1}{R\sqrt{t}}} \sum_{t=1}^{T} \frac{1}{t} \leq R \frac{\|\boldsymbol{x}^{\star}\|_{2}^{2} + 1 + \ln T}{4\sqrt{T+1} - 4},$$

where we used  $\sum_{t=1}^{T} \frac{1}{\sqrt{t}} \geq 2\sqrt{T+1} - 2$ .

I stressed the fact that the only meaningful way to define a regret is with respect to an arbitrary point in the feasible set. This is obvious in the case we consider unconstrained OLO, because the optimal competitor is unbounded. But, it is also true in unconstrained OCO. Let's see an example of this.

**Example 3.4.** Consider a problem of binary classification, with inputs  $z_i \in \mathbb{R}^d$  and outputs  $y_i \in \{-1,1\}$ . The loss function is the logistic loss:  $f(x,(z,y)) = \ln(1 + \exp(-y\langle z,x\rangle))$ . Suppose that you want to minimize the training error over a training set of N samples,  $\{(z_i,y_i)\}_{i=1}^N$ . Also, assume the maximum  $L_2$  norm of the samples is R. That is, we want to minimize

$$\min_{\boldsymbol{x}} F(\boldsymbol{x}) := \frac{1}{N} \sum_{i=1}^{N} \ln(1 + \exp(-y_i \langle \boldsymbol{z}_i, \boldsymbol{x} \rangle)).$$

So, run the reduction described in Theorem 3.1 for T iterations using OSD. In each iteration, construct  $\ell_t(\mathbf{x}) = \ln(1 + \exp(-y_t \langle \mathbf{z}_t, \mathbf{x} \rangle))$  sampling a training point uniformly at random from 1 to N. Set  $\mathbf{x}_1 = \mathbf{0}$  and  $\eta = \frac{1}{R\sqrt{T}}$ . We have that

$$\mathbb{E}\left[F\left(\frac{1}{T}\sum_{t=1}^{T}\boldsymbol{x}_{t}\right)\right] \leq \frac{R}{2\sqrt{T}} + \min_{\boldsymbol{u} \in \mathbb{R}^{d}}F(\boldsymbol{u}) + R\frac{\|\boldsymbol{u}\|^{2}}{2\sqrt{T}}.$$

In words, we will be  $\frac{R}{2\sqrt{T}}$  away from the optimal value of regularized empirical risk minimization problem, where the weight of the regularization is  $\frac{R}{2\sqrt{T}}$ . Now, let's consider the case that the training set is linearly separable, this means that the infimum of F is 0 and the optimal solution does not exist, i.e., it has norm equal to infinity. So, any convergence guarantee that depends on  $x^*$  would be vacuous. On the other hand, our guarantee above still makes perfectly sense.

Note that the above examples only deal with training error. However, in the next sections we show a more interesting application of the online-to-batch conversion, that is to directly minimize the generalization error. Moreover, we will show guarantees in high probability, rather than just in expectation.

#### 3.1.1 Bits on Concentration Inequalities

We will use a concentration inequality to prove the high probability guarantee, but we will need to go beyond the sum of i.i.d.random variables. In particular, we will use the concept of *martingales*.

**Definition 3.5** (Martingale). A sequence of random variables  $Z_1, Z_2, \ldots$  is called a martingale if for all  $t \geq 1$  it satisfies:

$$\mathbb{E}[|Z_t|] < \infty, \qquad \qquad \mathbb{E}[Z_{t+1}|Z_1, \dots, Z_t] = Z_t .$$

**Definition 3.6** (Supermartingale). A sequence of random variables  $Z_1, Z_2, ...$  is called a **supermartingale** if for all  $t \ge 1$  it satisfies:

$$\mathbb{E}[|Z_t|] < \infty,$$
  $\mathbb{E}[Z_{t+1}|Z_1, \dots, Z_t] \le Z_t.$ 

**Example 3.7.** Consider a fair coin  $c_t$  and a betting algorithm that bets  $|x_t|$  money on each round on the side of the coin equal to  $\operatorname{sign}(x_t)$ . We win or lose money 1:1, so the total money we won up to round t is  $Z_t = \sum_{i=1}^t c_i x_i$ .  $Z_1, \ldots, Z_t$  is a martingale. Indeed, we have

$$\mathbb{E}[Z_t|Z_1,\ldots,Z_{t-1}] = \mathbb{E}[Z_{t-1} + x_t c_t | Z_1,\ldots,Z_{t-1}] = Z_{t-1} + \mathbb{E}[x_t c_t | Z_1,\ldots,Z_{t-1}] = Z_{t-1}.$$

If we throw away part of the wealth in each round, we obtain a supermartingale.

For bounded martingales we can prove high probability guarantees as for bounded i.i.d. random variables. The following Theorem will be the key result we will need.

**Theorem 3.8** (Hoeffding-Azuma inequality). Let  $Z_0, \ldots, Z_T$  be a martingale of T random variables that satisfy  $|Z_t - Z_{t+1}| \le B, t = 1, \ldots, T-1$  almost surely. Then, we have

$$\mathbb{P}\{Z_T - Z_0 \ge \epsilon\} \le \exp\left(-\frac{\epsilon^2}{2B^2T}\right) .$$

Also, the same upper bounds hold on  $\mathbb{P}\{Z_0 - Z_T \ge \epsilon\}$ .

#### 3.1.2 High-Probability Guarantees for Online-to-Batch Conversion

We now show how the online-to-batch conversion we introduced can be strengthen to produce guarantees in high probability.

**Theorem 3.9.** Let  $\mathcal{V} \subset \mathbb{R}^d$ ,  $F(\boldsymbol{x}) = \mathbb{E}[f(\boldsymbol{x}, \boldsymbol{\xi})]$ , where the expectation is w.r.t.  $\boldsymbol{\xi}$  drawn from  $\rho$  with support over some set  $\mathcal{D}$ , and  $f: \mathcal{V} \times \mathcal{D} \to [0,1]$ . Draw T samples  $\boldsymbol{\xi}_1, \ldots, \boldsymbol{\xi}_T$  i.i.d. from  $\rho$  and construct the sequence of losses  $\ell_t(\boldsymbol{x}) = f(\boldsymbol{x}, \boldsymbol{\xi}_t)$ . Let  $\mathcal{A}$  any online learning algorithm over the losses  $\ell_t$  that outputs the sequence of predictions  $\boldsymbol{x}_1, \ldots, \boldsymbol{x}_{T+1}$  and guarantees  $\operatorname{Regret}_T(\boldsymbol{u}) \leq R(\boldsymbol{u}, T)$  for all  $\boldsymbol{u} \in \mathcal{V}$ , for a function  $R: \mathcal{V} \times \mathbb{N} \to \mathbb{R}$ . Then, we have with probability at least  $1 - \delta$ , it holds that

$$\frac{1}{T} \sum_{t=1}^{T} F(\boldsymbol{x}_t) \leq \min_{\boldsymbol{u} \in \mathcal{V}} F(\boldsymbol{u}) + \frac{R(\boldsymbol{u}, T)}{T} + 2\sqrt{\frac{2 \ln \frac{2}{\delta}}{T}}.$$

*Proof.* Define  $Z_t = \sum_{i=1}^t (F(\boldsymbol{x}_i) - \ell_i(\boldsymbol{x}_i))$  for  $t = 1, \dots, T$  and  $Z_0 = 0$ . We claim that  $Z_t$  is a martingale. In fact, we have

$$\mathbb{E}[\ell_t(\boldsymbol{x}_t)|\boldsymbol{\xi}_1,\ldots,\boldsymbol{\xi}_{t-1}] = \mathbb{E}[f(\boldsymbol{x}_t,\boldsymbol{\xi}_t)|\boldsymbol{\xi}_1,\ldots,\boldsymbol{\xi}_{t-1}] = F(\boldsymbol{x}_t),$$

where we used the fact that  $x_t$  depends only on  $\xi_1, \dots, \xi_{t-1}$  Hence, we have

$$\mathbb{E}[Z_{t+1}|Z_1,\ldots,Z_t] = Z_t + \mathbb{E}[F(\boldsymbol{x}_{t+1}) - \ell_{t+1}(\boldsymbol{x}_{t+1})|Z_1,\ldots,Z_t] = Z_t,$$

that proves our claim.

Hence, using Theorem 3.8, we have

$$\mathbb{P}\left\{\sum_{t=1}^{T} \left(F(\boldsymbol{x}_t) - \ell_t(\boldsymbol{x}_t)\right) \ge \epsilon\right\} = \mathbb{P}\left\{Z_T - Z_0 \ge \epsilon\right\} \le \exp\left(-\frac{\epsilon^2}{2T}\right).$$

This implies that, with probability at least  $1 - \delta/2$ , we have

$$\sum_{t=1}^{T} F(\boldsymbol{x}_t) \leq \sum_{t=1}^{T} \ell_t(\boldsymbol{x}_t) + \sqrt{2T \ln \frac{2}{\delta}},$$

or equivalently

$$\frac{1}{T} \sum_{t=1}^{T} F(x_t) \le \frac{1}{T} \sum_{t=1}^{T} \ell_t(x_t) + \sqrt{\frac{2 \ln \frac{2}{\delta}}{T}}.$$

We now use the definition of regret w.r.t. any u, to have

$$\frac{1}{T} \sum_{t=1}^{T} \ell_t(\boldsymbol{x}_t) = \frac{\operatorname{Regret}_T(\boldsymbol{u})}{T} + \frac{1}{T} \sum_{t=1}^{T} \ell_t(\boldsymbol{u}) \leq \frac{R(\boldsymbol{u}, T)}{T} + \frac{1}{T} \sum_{t=1}^{T} \ell_t(\boldsymbol{u}) .$$

The last step is to upper bound with high probability  $\frac{1}{T}\sum_{t=1}^T \ell_t(\boldsymbol{u})$  with  $F(\boldsymbol{u})$ . This is easier than the previous upper bound because we set  $\boldsymbol{u}$  to be the fixed vector that minimizes  $F(\boldsymbol{x}) + \frac{R(\boldsymbol{x},T)}{T}$  in  $\mathcal{V}$ . So,  $\ell_t(\boldsymbol{u})$  are i.i.d. random variables and for sure  $Z_t = \sum_{i=1}^t \left(F(\boldsymbol{u}) - \ell_i(\boldsymbol{u})\right)$  forms a martingale. So, reasoning as above, we have that with probability at least  $1 - \delta/2$  it holds that

$$\frac{1}{T} \sum_{t=1}^{T} \ell_t(\boldsymbol{u}) \leq F(\boldsymbol{u}) + \sqrt{\frac{2 \ln \frac{2}{\delta}}{T}}.$$

Putting all together and using the union bound, we have the stated bound.

The theorem above upper bounds the average value of the T different solutions, while we are interested in producing a single solution. If F is a convex function and  $\mathcal{V}$  is convex, than we can lower bound the l.h.s. of the inequalities in the theorem with the function evaluated on the average of the  $x_t$ . That is

$$F\left(\frac{1}{T}\sum_{t=1}^{T} \boldsymbol{x}_{t}\right) \leq \frac{1}{T}\sum_{t=1}^{T} F(\boldsymbol{x}_{t}).$$

### 3.2 Application: Agnostic PAC Learning

In this section, we show another application of online-to-batch methods to obtain statistical learning guarantees. Here, we assume to have a prediction strategy  $\phi_x$  parametrized by a vector x and we want to learn the relationship between an input z and its associated label y. Moreover, we will assume that (z, y) is drawn from a joint probability distribution

 $\rho$ . Also, we are equipped with a loss function that measures how good is our prediction  $\hat{y} = \phi_{x}(z)$  compared to the true label y, that is  $\ell(\hat{y}, y)$ . So, learning the relationship can be cast as minimizing the expected loss of our predictor

$$\min_{\boldsymbol{x} \in \mathcal{V}} \mathbb{E}_{(\boldsymbol{z}, y) \sim \rho} [\ell(\phi_{\boldsymbol{x}}(\boldsymbol{z}), y)].$$

In machine learning terms, the object above is nothing else than the test error of our predictor.

Note that the above setting assumes labeled samples, but we can generalize it even more considering the *Vapnik's* general setting of learning, where we collapse the prediction function and the loss in a unique function. This allows, for example, to treat supervised and unsupervised learning in the same unified way. So, we want to minimize the *risk* 

$$\min_{\boldsymbol{x} \in \mathcal{V}} \left( \operatorname{Risk}(\boldsymbol{x}) := \mathbb{E}_{\boldsymbol{\xi} \sim \rho}[f(\boldsymbol{x}, \boldsymbol{\xi})] \right),$$

where  $\rho$  is an unknown distribution over  $\mathcal{D}$  and  $f: \mathbb{R}^d \times \mathcal{D} \to \mathbb{R}$  is measurable w.r.t. the second argument. Also, the set  $\mathcal{F}$  of all predictors that can be expressed by vectors  $\mathbf{x}$  in  $\mathcal{V}$  is called the *hypothesis class*.

**Example 3.10.** In a linear regression task where the loss is the square loss, we have  $\boldsymbol{\xi} = (\boldsymbol{z}, y) \in \mathbb{R}^d \times \mathbb{R}$  and  $\phi_{\boldsymbol{x}}(\boldsymbol{z}) = \langle \boldsymbol{z}, \boldsymbol{x} \rangle$ . Hence,  $f(\boldsymbol{x}, \boldsymbol{\xi}) = (\langle \boldsymbol{z}, \boldsymbol{x} \rangle - y)^2$ .

**Example 3.11.** In linear binary classification where the loss is the hinge loss, we have  $\boldsymbol{\xi} = (\boldsymbol{z}, y) \in \mathbb{R}^d \times \{-1, 1\}$  and  $\phi_{\boldsymbol{x}}(\boldsymbol{z}) = \langle \boldsymbol{z}, \boldsymbol{x} \rangle$ . Hence,  $f(\boldsymbol{x}, \boldsymbol{\xi}) = \max(1 - y\langle \boldsymbol{z}, \boldsymbol{x} \rangle, 0)$ .

**Example 3.12.** In binary classification with a neural network with the logistic loss, we have  $\boldsymbol{\xi} = (\boldsymbol{x}, y) \in \mathbb{R}^d \times \{-1, 1\}$  and  $\phi_{\boldsymbol{x}}$  is the network corresponding to the weights  $\boldsymbol{x}$ . Hence,  $f(\boldsymbol{x}, \boldsymbol{\xi}) = \ln(1 + \exp(-y\phi_{\boldsymbol{x}}(\boldsymbol{z})))$ .

The key difficulty of the above problem is that we do not know the distribution  $\rho$ . Hence, there is no hope to exactly solve this problem. Instead, we are interested in understanding what is the best we can do if we have access to T samples drawn i.i.d. from  $\rho$ . More in details, we want to upper bound the excess risk

$$\operatorname{Risk}(\boldsymbol{x}_T) - \min_{\boldsymbol{x}} \operatorname{Risk}(\boldsymbol{x}),$$

where  $x_T$  is a predictor that was *learned* using T samples.

It should be clear that this is just an optimization problem and the one above is just the suboptimality gap. In this view, the objective of machine learning can be considered as a particular optimization problem.

**Remark 3.13.** Note that this is not the only way to approach the problem of learning. Indeed, the regret minimization model is an alternative model to learning. Moreover, another approach would be to try to estimate the distribution  $\rho$  and then solve the risk minimization problem. No approach is superior to the other and each of them has its pros and cons.

Given that we have access to the distribution  $\rho$  through samples drawn from it, any procedure we might think to use to minimize the risk will be stochastic in nature. This means that we cannot assure a deterministic guarantee. Instead, we can try to prove that with high probability our minimization procedure will return a solution that is close to the minimizer of the risk. It is also intuitive that the precision and probability we can guarantee must depend on how many samples we draw from  $\rho$ .

Quantifying the dependency of precision and probability of failure on the number of samples used is the objective of the **Agnostic Probably Approximately Correct** (PAC) framework, where the keyword "agnostic" refers to the fact that we do not assume anything on the best possible predictor. More in details, given a precision parameter  $\epsilon$  and a probability of failure  $\delta$ , we are interested in characterizing the *sample complexity of the hypothesis class*  $\mathcal F$  that is defined as the number of samples T necessary to guarantee with probability at least  $1-\delta$  that the best learning algorithm using the hypothesis class  $\mathcal F$  outputs a solution  $x_T$  that has an excess risk upper bounded by  $\epsilon$ . Note that the sample complexity does not depend on  $\rho$ , so it is a worst-case measure w.r.t. all the possible distributions. This makes sense if you think that we know nothing about the distribution  $\rho$ , so if your guarantee holds for the worst distribution it will also hold for any other distribution. Mathematically, we will say that the hypothesis class is agnostic PAC-learnable is such sample complexity function exists.

**Definition 3.14** (Agnostic-PAC-learnable). We will say that a function class  $\mathcal{F} = \{f(\boldsymbol{x},\cdot) : \boldsymbol{x} \in \mathbb{R}^d\}$  is Agnostic-PAC-learnable if there exists an algorithm  $\mathcal{A}$  and a function  $T(\epsilon,\delta) : \mathbb{R} \times [0,1] \to \mathbb{N}$  such that when  $\mathcal{A}$  is used with  $T \geq T(\epsilon,\delta)$  samples drawn from  $\rho$ , with probability at least  $1-\delta$  the solution  $\boldsymbol{x}_T$  returned by the algorithm has excess risk at most  $\epsilon$ .

Note that the Agnostic PAC learning setting does not say what is the procedure we should follow to find such sample complexity. The approach most commonly used in machine learning to solve the learning problem is the so-called *Empirical Risk Minimization (ERM)* procedure. It consist of drawing T samples i.i.d. from  $\rho$  and minimizing the *empirical risk* defined as

$$\widehat{\mathrm{Risk}}(\boldsymbol{x}) := \min_{\boldsymbol{x} \in \mathcal{V}} \; \frac{1}{T} \sum_{t=1}^T f(\boldsymbol{x}; \boldsymbol{\xi}_t) \; .$$

The minimizer  $\hat{x}_T$  is called the *empirical risk minimizer*. In words, ERM is nothing else than the minimization of the some loss function on a training set. However, in many interesting cases we can have that  $\operatorname{argmin}_{x \in \mathcal{V}} \frac{1}{T} \sum_{t=1}^T f(x; \boldsymbol{\xi}_t)$  can be very far from the true optimum  $\operatorname{argmin}_{x \in \mathcal{V}} \mathbb{E}[f(x; \boldsymbol{\xi})]$ , even with an infinite number of samples! So, we need to modify the ERM formulation in some way, e.g., using a *regularization* term, a Bayesian prior of  $\boldsymbol{x}$ , or more generally find conditions under which ERM works.

It is worth stressing that sometimes people are concerned with the difference between the training error and the test error of the trained predictor, i.e.,  $\widehat{\text{Risk}}(\hat{x}_T) - \text{Risk}(\hat{x}_T)$ . However, this gap can be large without implying anything on the risk of the trained predictor.

The ERM approach is so widespread that machine learning itself is often wrongly identified with some kind of minimization of the training error. We now show that ERM is not the entire world of ML, showing that the existence of a no-regret algorithm, that is an online learning algorithm with sublinear regret, guarantee Agnostic-PAC learnability. More in details, we will show that an online algorithm with sublinear regret can be used to solve machine learning problems. This is not just a curiosity, for example this gives rise to computationally efficient parameter-free algorithms, that can be achieved through ERM only running a two-step procedure, i.e., running ERM with different parameters and selecting the best solution among them.

We can use Theorem 3.9, to produce a solution with small risk. In particular, if the risk is convex, we can output the average of the  $x_t$ , using Jensen's inequality.

If the risk is not a convex function, we need a different way. An alternative solution is to construct a *stochastic* classifier that samples one of the  $x_t$  with uniform probability and predicts with it. For this classifier, we immediately have

$$\operatorname{Risk}(\{\boldsymbol{x}_1,\ldots,\boldsymbol{x}_T\}) = \frac{1}{T} \sum_{t=1}^T \operatorname{Risk}(\boldsymbol{x}_t),$$

where the expectation in the definition of the risk of the stochastic classifier is also with respect to the random index.

Yet another way, is to select among the T predictors, the one with the smallest risk. This works because the average is lower bounded by the minimum. This is easily achieved using T/2 samples for the online learning procedure and T/2 samples to generate a validation set to evaluate the solution and pick the best one. The following Theorem shows that selecting the predictor with the smallest empirical risk on a validation set will give us a predictor close to the best one with high probability.

**Theorem 3.15.** Let  $\mathcal{V} \subset \mathbb{R}^d$ ,  $\operatorname{Risk}(\boldsymbol{x}) = \mathbb{E}[f(\boldsymbol{x},\boldsymbol{\xi})]$ , where the expectation is w.r.t.  $\boldsymbol{\xi}$  drawn from  $\rho$  with support over some set  $\mathcal{D}$ , and  $f: \mathcal{V} \times \mathcal{D} \to [0,1]$ . We have a finite set of vectors  $S = \{\boldsymbol{x}_1, \dots, \boldsymbol{x}_{|S|}\}$  and T random vectors  $\boldsymbol{\xi}_1, \dots, \boldsymbol{\xi}_T$  drawn i.i.d. from  $\rho$ . Denote by  $\hat{\boldsymbol{x}} = \operatorname{argmin}_{\boldsymbol{x} \in S} \widehat{\operatorname{Risk}}(\boldsymbol{x})$ , where  $\widehat{\operatorname{Risk}}(\boldsymbol{x}) = \frac{1}{T} \sum_{t=1}^T f(\boldsymbol{x}, \boldsymbol{\xi}_t)$ . Then, with probability at least  $1 - \delta$ , we have

$$\operatorname{Risk}(\hat{\boldsymbol{x}}) \leq \min_{\boldsymbol{x} \in S} \operatorname{Risk}(\boldsymbol{x}) + 2\sqrt{\frac{2\ln(2|S|/\delta)}{T}} \ .$$

*Proof.* We want to calculate the probability that the hypothesis that minimizes the validation error is far from the best hypothesis in the set. We cannot do it directly because we do not have the required independence to use a concentration

inequality. Instead, we will upper bound the probability that there exists at least one function whose empirical risk is far from the risk. So, using the union bound, we have

$$\mathbb{P}\left\{\exists \boldsymbol{x} \in S: |\operatorname{Risk}(\boldsymbol{x}) - \widehat{\operatorname{Risk}}(\boldsymbol{x})| > \frac{\epsilon}{2}\right\} \leq \sum_{i=1}^{|S|} \mathbb{P}\left\{|\operatorname{Risk}(\boldsymbol{x}_i) - \widehat{\operatorname{Risk}}(\boldsymbol{x}_i)| > \frac{\epsilon}{2}\right\} \leq 2|S| \exp\left(-\frac{\epsilon^2 T}{8}\right).$$

Hence, with probability at least  $1 - \delta$ , we have that

$$|\operatorname{Risk}(\boldsymbol{x}) - \widehat{\operatorname{Risk}}(\boldsymbol{x})| \leq \frac{\epsilon}{2}, \ \forall \boldsymbol{x} \in S,$$

where 
$$\epsilon = 2\sqrt{\frac{2\ln(2|S|/\delta)}{T}}$$
.

We are now able to upper bound the risk of  $\hat{x}$ , just using the fact that the above applies to  $\hat{x}$  too. Defining  $x^* = \operatorname{argmin}_{x \in S} \operatorname{Risk}(x)$ , we have

$$\operatorname{Risk}(\hat{x}) \leq \widehat{\operatorname{Risk}}(\hat{x}) + \epsilon/2 \leq \widehat{\operatorname{Risk}}(x^*) + \epsilon/2 \leq \operatorname{Risk}(x^*) + \epsilon,$$

where in the second inequality we used the fact that  $\hat{x}$  minimizes the empirical risk.

Using this theorem, we can use T/2 samples for the training and T/2 samples for the validation, where  $T \geq 2$ . Denoting by  $\hat{x}_T$  the predictor with the best empirical risk on the validation set among the T/2 generated during the online procedure, we have with probability at least  $1 - 2\delta$  that

$$\operatorname{Risk}(\hat{\boldsymbol{x}}_T) \leq \min_{\boldsymbol{u} \in \mathcal{V}} \operatorname{Risk}(\boldsymbol{u}) + \frac{2R(\boldsymbol{u}, T/2)}{T} + 8\sqrt{\frac{\ln(T/\delta)}{T}}$$
.

It is important to note that with any of the above three methods to produce one predictor from the T generated ones by the online learning procedure, the sample complexity guarantee we get matches the one we would have obtained by ERM, up to polylogarithmic factors. In other words, there is nothing special about ERM compared to the online learning approach to statistical learning. Moreover, ERM implies the existence of a hypothetical procedure that perfectly minimizes the training error. In reality, we should take into account the optimization error in the analysis of ERM. On the other hand, in the online learning approach we have a guarantee directly for the computed solution.

Another important point is that the above guarantee does not imply the existence of online learning algorithms with sublinear regret for any learning problem. It just says that, if it exists, it can be used in the statistical setting too.

## 3.3 History Bits

The specific shape of Theorem 3.1 is new, but I would not be surprised if it appeared somewhere in the literature. In particular, the uniform averaging is from Cesa-Bianchi et al. [2004], but was proposed for the absolute loss in Blum et al. [1999]. The non-uniform averaging of Example 3.3 is from Zhang [2004], even if there it is not proposed explicitly as an online-to-batch conversion.

A more recent method to do online-to-batch conversion has been introduced in Cutkosky [2019a], that independently rediscovered and generalized the averaging method in Nesterov and Shikhman [2015]. This new method allows to prove the convergence of the last iterate rather than the one of the weighted average, with a small change in any online learning algorithm.

Theorem 3.9 is from Cesa-Bianchi et al. [2004], but here I used a second concentration to state it in terms of the competitor's true risk rather than its empirical risk. Theorem 3.15 is nothing else than the Agnostic PAC learning guarantee for ERM for hypothesis classes with finite cardinality. Cesa-Bianchi et al. [2004] also gives an alternative procedure to select a single hypothesis among the T generated during the online procedure that does not require splitting the data in training and validation. However, the obtained guarantee matches the one we have proved.

## 3.4 Exercises

**Problem 3.1.** Derive an explicit rate of convergence for SGD in Example 3.4 by upper bounding the value of the minimum on the right hand side of the convergence rate guarantee. Hint: see Ji and Telgarsky [2019].

## **Chapter 4**

## **Beyond** $\sqrt{T}$ **Regret**

## 4.1 Strong Convexity and Online Subgradient Descent

Let's now go back to online convex optimization theory. The example in the first chapter showed us that it is possible to get logarithmic regret in time. However, we saw that we get only  $\sqrt{T}$ -regret with Online Subgradient Descent (OSD) on the same game. What is the reason? It turns out that the losses in the first game,  $\ell_t(x) = (x-y_t)^2$  on [0,1], are not just Lipschitz. They also posses some *curvature* that can be exploited to achieve a better regret. In a moment we will see that the only change we will need to OSD is a different learning rate, dictated as usual by the regret analysis.

The key concept we will need is the one of *strong convexity*.

## 4.1.1 Convex Analysis Bits: Strong Convexity

Here, we introduce a stronger concept of convexity, that allows to build better lower bound to a function. Instead of the linear lower bound achievable through the use of subgradients, we will make use of *quadratic* lower bound.

**Definition 4.1** (Strongly Convex Function). Let  $\lambda \geq 0$ . A proper function  $f: \mathcal{X} \to (-\infty, +\infty]$  is  $\lambda$ -strongly convex w.r.t.  $\|\cdot\|$  over a convex set  $\mathcal{V} \subseteq \operatorname{dom} f$  if

$$f(\alpha \boldsymbol{x} + (1 - \alpha)\boldsymbol{y}) \le \alpha f(\boldsymbol{x}) + (1 - \alpha)f(\boldsymbol{y}) - \frac{1}{2}\lambda\alpha(1 - \alpha)\|\boldsymbol{x} - \boldsymbol{y}\|^2,$$

for all  $x, y \in V$  and all  $\alpha \in (0, 1)$ .

We will also say that f is strongly convex in V, if there exists  $\lambda > 0$  and a norm such that the above holds.

From the definition, it is clear that if a function is  $\lambda$ -strongly convex, it is also  $\lambda'$ -strongly convex for any  $0 \le \lambda' < \lambda$ . Moreover, 0-strong convexity is just the definition of convex function.

We can also obtain an equivalent characterization in terms of subgradients.

**Lemma 4.2.** Let  $\lambda \geq 0$ . We have that  $f: \mathcal{X} \to (-\infty, +\infty]$  is  $\lambda$ -strongly convex over a convex set  $\mathcal{V} \subseteq \text{dom } \partial f$  w.r.t.  $\|\cdot\|$  iff

$$\forall \boldsymbol{x}, \boldsymbol{y} \in \mathcal{V}, \boldsymbol{g} \in \partial f(\boldsymbol{y}), \quad f(\boldsymbol{x}) \geq f(\boldsymbol{y}) + \langle \boldsymbol{g}, \boldsymbol{x} - \boldsymbol{y} \rangle + \frac{\lambda}{2} \|\boldsymbol{x} - \boldsymbol{y}\|^2.$$

*Proof.* Let's first assume that f is  $\lambda$ -strongly convex over  $\mathcal{V}$  w.r.t.  $\|\cdot\|$ . Then, for any  $\alpha \in (0,1)$  and any  $\mathbf{g} \in \partial f(\mathbf{y})$ , we have

$$\langle \boldsymbol{g}, \boldsymbol{x} - \boldsymbol{y} \rangle \leq \frac{f(\alpha \boldsymbol{x} + (1 - \alpha) \boldsymbol{y}) - f(\boldsymbol{y})}{\alpha} \leq f(\boldsymbol{x}) - f(\boldsymbol{y}) - \frac{1}{2}\lambda(1 - \alpha)\|\boldsymbol{x} - \boldsymbol{y}\|^2$$
.

Taking the limit for  $\alpha$  to 0, we obtain the statement.

Let's now assume that the inequality in the lemma holds and let's prove that f is  $\lambda$ -strongly convex. Setting  $\mathbf{v} = \alpha \mathbf{x} + (1 - \alpha)\mathbf{y}$ , for any  $\mathbf{g} \in \partial f(\mathbf{v})$ , we have

$$\langle \boldsymbol{g}, \boldsymbol{x} - \boldsymbol{v} \rangle \le f(\boldsymbol{x}) - f(\boldsymbol{v}) - \frac{\lambda}{2} \|\boldsymbol{x} - \boldsymbol{v}\|^2,$$
  
 $\langle \boldsymbol{g}, \boldsymbol{y} - \boldsymbol{v} \rangle \le f(\boldsymbol{y}) - f(\boldsymbol{v}) - \frac{\lambda}{2} \|\boldsymbol{y} - \boldsymbol{v}\|^2.$ 

Summing these two inequalities with coefficients  $\alpha$  and  $1 - \alpha$ , we have

$$0 = \langle \boldsymbol{g}, \alpha \boldsymbol{x} - \alpha \boldsymbol{v} + (1 - \alpha) \boldsymbol{y} - (1 - \alpha) \boldsymbol{v} \rangle$$

$$\leq \alpha f(\boldsymbol{x}) - \alpha f(\boldsymbol{v}) + (1 - \alpha) f(\boldsymbol{y}) - (1 - \alpha) f(\boldsymbol{v}) - \alpha \frac{\lambda}{2} \|\boldsymbol{x} - \boldsymbol{v}\|^2 - (1 - \alpha) \frac{\lambda}{2} \|\boldsymbol{y} - \boldsymbol{v}\|^2$$

$$= \alpha f(\boldsymbol{x}) - f(\alpha \boldsymbol{x} + (1 - \alpha) \boldsymbol{y}) + (1 - \alpha) f(\boldsymbol{y}) - \alpha \frac{\lambda}{2} \|\boldsymbol{x} - \alpha \boldsymbol{x} - (1 - \alpha) \boldsymbol{y}\|^2 - (1 - \alpha) \frac{\lambda}{2} \|\boldsymbol{y} - \alpha \boldsymbol{x} - (1 - \alpha) \boldsymbol{y}\|^2$$

$$= \alpha f(\boldsymbol{x}) - f(\alpha \boldsymbol{x} + (1 - \alpha) \boldsymbol{y}) + (1 - \alpha) f(\boldsymbol{y}) - \alpha \frac{\lambda}{2} (1 - \alpha)^2 \|\boldsymbol{x} - \boldsymbol{y}\|^2 - (1 - \alpha) \frac{\lambda}{2} \alpha^2 \|\boldsymbol{x} - \boldsymbol{y}\|^2$$

$$= \alpha f(\boldsymbol{x}) - f(\alpha \boldsymbol{x} + (1 - \alpha) \boldsymbol{y}) + (1 - \alpha) f(\boldsymbol{y}) - \alpha (1 - \alpha) \frac{\lambda}{2} \|\boldsymbol{x} - \boldsymbol{y}\|^2.$$

In words, the lemma above tells us that a strongly convex function can be lower bounded by a quadratic, where the linear term is the usual one constructed through the subgradient, and the quadratic term depends on the strong convexity. Hence, we have a tighter lower bound to the function w.r.t. simply using convexity. This is what we would expect using a Taylor expansion on a twice-differentiable convex function and lower bounding the smallest eigenvalue of the Hessian. Indeed, we have the following Theorem.

**Theorem 4.3.** Let  $f: \mathbb{R}^d \to (-\infty, +\infty]$  be proper and convex. Then, f is  $\lambda$ -strongly convex with respect to  $\|\cdot\|$  in int dom f iff

$$\langle \boldsymbol{g}_{\boldsymbol{x}} - \boldsymbol{g}_{\boldsymbol{y}}, \boldsymbol{x} - \boldsymbol{y} \rangle \ge \lambda \|\boldsymbol{x} - \boldsymbol{y}\|^2, \ \forall \boldsymbol{g}_{\boldsymbol{x}} \in \partial f(\boldsymbol{x}), \boldsymbol{g}_{\boldsymbol{y}} \in \partial f(\boldsymbol{y}).$$
 (4.1)

Moreover, if f is also twice differentiable in an open set containing its domain, a sufficient condition for  $\lambda$ -strong convexity in dom f w.r.t.  $\|\cdot\|$  is that for all x, y we have

$$\langle \nabla^2 f(\boldsymbol{x}) \boldsymbol{y}, \boldsymbol{y} \rangle \ge \lambda \|\boldsymbol{y}\|^2, \tag{4.2}$$

where  $\nabla^2 f(x)$  is the Hessian matrix of f at x.

*Proof.* For the first statement, first assume that f is  $\lambda$ -strongly convex with respect to  $\|\cdot\|$ . Then, from Lemma 4.2, we have

$$\langle \boldsymbol{g}_{\boldsymbol{x}}, \boldsymbol{y} - \boldsymbol{x} \rangle \le f(\boldsymbol{x}) - f(\boldsymbol{y}) - \frac{\lambda}{2} \|\boldsymbol{x} - \boldsymbol{y}\|^2, \ \forall \boldsymbol{g}_{\boldsymbol{x}} \in \partial f(\boldsymbol{x}),$$
  
 $\langle \boldsymbol{g}_{\boldsymbol{y}}, \boldsymbol{x} - \boldsymbol{y} \rangle \le f(\boldsymbol{y}) - f(\boldsymbol{x}) - \frac{\lambda}{2} \|\boldsymbol{x} - \boldsymbol{y}\|^2, \ \forall \boldsymbol{g}_{\boldsymbol{y}} \in \partial f(\boldsymbol{y}).$ 

Summing the two inequalities, we have the stated bound.

Now, assume that the (4.1) holds. Define  $h(\alpha)=f(\boldsymbol{y}+\alpha(\boldsymbol{x}-\boldsymbol{y})),$   $\boldsymbol{w}_{\alpha}=\boldsymbol{y}+\alpha(\boldsymbol{x}-\boldsymbol{y}),$  and  $\boldsymbol{g}_{\boldsymbol{w}_{\alpha}}\in\partial f(\boldsymbol{w}_{\alpha}).$  From Theorem 2.27, we have  $\langle \boldsymbol{g}_{\boldsymbol{w}_{\alpha}},\boldsymbol{x}-\boldsymbol{y}\rangle\in\partial h(\alpha).$  Moreover, we have

$$\langle \boldsymbol{g}_{\boldsymbol{w}_{\alpha}}, \boldsymbol{x} - \boldsymbol{y} \rangle - \langle \boldsymbol{g}_{\boldsymbol{y}}, \boldsymbol{x} - \boldsymbol{y} \rangle = \frac{1}{\alpha} \langle \boldsymbol{g}_{\boldsymbol{w}_{\alpha}} - \boldsymbol{g}_{\boldsymbol{y}}, \boldsymbol{w}_{\alpha} - \boldsymbol{y} \rangle \ge \frac{\lambda}{\alpha} \|\boldsymbol{w}_{\alpha} - \boldsymbol{y}\|^2 = \lambda \alpha \|\boldsymbol{x} - \boldsymbol{y}\|^2,$$

where we used (4.1) in the inequality. Using the Fundamental Theorem of Calculus (Theorem A.1) and this last inequality, we have

$$f(\boldsymbol{x}) - f(\boldsymbol{y}) - \langle \boldsymbol{g}_{\boldsymbol{y}}, \boldsymbol{x} - \boldsymbol{y} \rangle = h(1) - h(0) - \langle \boldsymbol{g}_{\boldsymbol{y}}, \boldsymbol{x} - \boldsymbol{y} \rangle = \int_0^1 (\langle \boldsymbol{g}_{\boldsymbol{w}_{\alpha}}, \boldsymbol{x} - \boldsymbol{y} \rangle - \langle \boldsymbol{g}_{\boldsymbol{y}}, \boldsymbol{x} - \boldsymbol{y} \rangle) \, \mathrm{d}\alpha$$
$$\geq \frac{\lambda}{2} \|\boldsymbol{x} - \boldsymbol{y}\|^2 \, .$$

Hence, by Lemma 4.2, f is  $\lambda$ -strongly convex with respect to  $\|\cdot\|$ .

For the second statement, assume that f is twice differentiable and (4.2) holds. Then,

$$h''(\alpha) = \langle \nabla^2 f(\boldsymbol{y} + \alpha(\boldsymbol{x} - \boldsymbol{y}))(\boldsymbol{x} - \boldsymbol{y}), \boldsymbol{x} - \boldsymbol{y} \rangle \ge \lambda \|\boldsymbol{x} - \boldsymbol{y}\|^2$$
.

Moreover, from the Taylor's remainder theorem, we have that  $h(1) = h(0) + h'(0) + h''(\beta)/2$ , where  $\beta \in [0, 1]$ . So, we have

$$f(x) = h(1) = h(0) + h'(0) + h''(\beta)/2 \ge f(y) + \langle \nabla f(y), x - y \rangle + \frac{\lambda}{2} ||x - y||^2,$$

which, by Lemma 4.2, implies that f is  $\lambda$ -strongly convex with respect to  $\|\cdot\|$ .

However, a strongly convex function does not need to be twice differentiable. Indeed, we do not even need plain differentiability. Hence, the use of the subgradient implies that the quadratic lower bound does not have to be uniquely determined, as in the next Example.

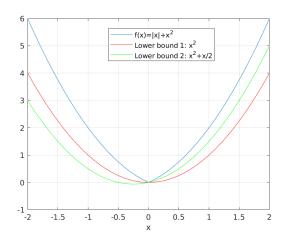

Figure 4.1: Possible lower bounds to the strongly convex non-differentiable function  $f(x) = |x| + x^2$ .

**Example 4.4.** Consider the strongly convex function  $f(x) = |x| + x^2$ . In Figure 4.1, we show two possible quadratic lower bounds to the function in x = 0.

We also have the following useful property on the sum of strongly convex functions.

**Theorem 4.5.** Let  $f: \mathbb{R}^d \to (-\infty, +\infty]$  be  $\mu_1$ -strongly convex and  $g: \mathbb{R}^d \to (-\infty, +\infty]$  a  $\mu_2$ -strongly convex function in a non-empty convex set  $\mathcal{V} \subseteq \operatorname{int} \operatorname{dom} f \cap \operatorname{int} \operatorname{dom} g$  w.r.t.  $\|\cdot\|$ . Then, f+g is  $\mu_1 + \mu_2$ -strongly convex in  $\mathcal{V}$  w.r.t.  $\|\cdot\|$ .

*Proof.* From the assumption on V and Theorem 2.22, we have that the subdifferential set of the sum is equal to the sum of the subdifferential sets. Hence, the proof is immediate from Lemma 4.2.

**Example 4.6.** Let  $f(x) = \frac{1}{2} ||x||_2^2$ . Using Theorem 4.3, we have that f is 1-strongly convex w.r.t.  $||\cdot||_2$  in  $\mathbb{R}^d$ .

## 4.1.2 Online Subgradient Descent for Strongly Convex Losses

**Theorem 4.7.** Let V be a non-empty closed convex set in  $\mathbb{R}^d$ . Assume that the functions  $\ell_t : V \to \mathbb{R}$  are  $\mu_t$ -strongly convex w.r.t  $\|\cdot\|_2$  and subdifferentiable in V, where  $\mu_t > 0$ . Use OSD in Algorithm 2.2 with stepsizes equal to  $\eta_t = \frac{1}{\sum_{i=1}^t \mu_i}$ . Then, for any  $\mathbf{u} \in V$ , we have the following regret guarantee

$$\sum_{t=1}^{T} \ell_t(\boldsymbol{x}_t) - \sum_{t=1}^{T} \ell_t(\boldsymbol{u}) \le \frac{1}{2} \sum_{t=1}^{T} \frac{\|\boldsymbol{g}_t\|_2^2}{\sum_{t=1}^{t} \mu_i}.$$

*Proof.* From the assumption of  $\mu_t$ -strong convexity of the functions  $\ell_t$ , we have that

$$\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u}) \leq \langle \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{u} \rangle - \frac{\mu_t}{2} \|\boldsymbol{x}_t - \boldsymbol{u}\|_2^2$$
.

From the fact that  $\eta_t = \frac{1}{\sum_{i=1}^t \mu_i}$ , we have

$$\frac{1}{2\eta_1} - \frac{\mu_1}{2} = 0,$$

$$\frac{1}{2\eta_t} - \frac{\mu_t}{2} = \frac{1}{2\eta_{t-1}}, \ t = 2, \dots, T.$$

Hence, use Lemma 2.30 and sum from t = 1, ..., T, to obtain

$$\sum_{t=1}^{T} \left( \ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u}) \right) \leq \sum_{t=1}^{T} \left( \frac{1}{2\eta_t} \| \boldsymbol{x}_t - \boldsymbol{u} \|_2^2 - \frac{1}{2\eta_t} \| \boldsymbol{x}_{t+1} - \boldsymbol{u} \|_2^2 - \frac{\mu_t}{2} \| \boldsymbol{x}_t - \boldsymbol{u} \|^2 + \frac{\eta_t}{2} \| \boldsymbol{g}_t \|_2^2 \right) \\
= -\frac{1}{2\eta_1} \| \boldsymbol{x}_2 - \boldsymbol{u} \|_2^2 + \sum_{t=2}^{T} \left( \frac{1}{2\eta_{t-1}} \| \boldsymbol{x}_t - \boldsymbol{u} \|_2^2 - \frac{1}{2\eta_t} \| \boldsymbol{x}_{t+1} - \boldsymbol{u} \|_2^2 \right) + \sum_{t=1}^{T} \frac{\eta_t}{2} \| \boldsymbol{g}_t \|_2^2.$$

Observing that the first sum on the right hand side is a telescopic sum, we have the stated bound.

**Remark 4.8.** Notice that this theorem implicitly requires a bounded domain, otherwise the loss functions will not be Lipschitz given that they are also strongly convex.

**Corollary 4.9.** Under the assumptions of Theorem 4.7, if in addiction we have  $\mu_t = \mu > 0$  and  $\ell_t$  is L-Lipschitz w.r.t.  $\|\cdot\|_2$ , for  $t = 1, \ldots, T$ , then we have

$$\sum_{t=1}^{T} \ell_t(\boldsymbol{x}_t) - \sum_{t=1}^{T} \ell_t(\boldsymbol{u}) \le \frac{L^2}{2\mu} (1 + \ln T) .$$

**Remark 4.10.** Corollary 4.9 does not imply that for any finite T the regret will be smaller than using learning rates  $\propto \frac{1}{L\sqrt{t}}$ . Instead, asymptotically the regret in Corollary 4.9 is always better than to one of OSD with Lipschitz losses.

**Example 4.11.** Consider once again the example in the first chapter:  $\ell_t(x) = (x - y_t)^2$ . Note that the loss functions are 2-strongly convex w.r.t.  $|\cdot|$ . Hence, setting  $\eta_t = \frac{1}{2t}$  and  $\ell_t'(x) = 2(x - y_t)$  gives a regret of  $\ln(T) + 1$ .

Let's now use again the online-to-batch conversion on strongly convex stochastic problems.

**Example 4.12.** As done before, we can use the online-to-batch conversion to use Corollary 4.9 to obtain stochastic subgradient descent algorithms for strongly convex stochastic functions. For example, consider the classic Support Vector Machine objective

$$\min_{\boldsymbol{x}} F(\boldsymbol{x}) := \frac{\lambda}{2} \|\boldsymbol{x}\|_2^2 + \frac{1}{N} \sum_{i=1}^N \max(1 - y_i \langle \boldsymbol{z}_i, \boldsymbol{x} \rangle, 0),$$

or any other regularized formulation like regularized logistic regression:

$$\min_{\boldsymbol{x}} F(\boldsymbol{x}) := \frac{\lambda}{2} \|\boldsymbol{x}\|_2^2 + \frac{1}{N} \sum_{i=1}^{N} \ln(1 + \exp(-y_i \langle \boldsymbol{z}_i, \boldsymbol{x} \rangle)),$$

where  $z_i \in \mathbb{R}^d$ ,  $||z_i||_2 \le R$ , and  $y_i \in \{-1,1\}$ . First, notice that the minimizer of both expressions has to be in the  $L_2$  ball of radius proportional to  $\sqrt{\frac{1}{\lambda}}$  (proof left as exercise). Hence, we can set  $\mathcal{V}$  equal to this set. Then, setting

 $\ell_t(\boldsymbol{x}) = \frac{\lambda}{2} \|\boldsymbol{x}\|_2^2 + \max(1 - y_i \langle \boldsymbol{z}_i, \boldsymbol{x} \rangle, 0) \text{ or } \ell_t(\boldsymbol{x}) = \frac{\lambda}{2} \|\boldsymbol{x}\|_2^2 + \ln(1 + \exp(-y_i \langle \boldsymbol{z}_i, \boldsymbol{x} \rangle)) \text{ results in } \lambda\text{-strongly convex loss functions. Using Corollary 4.9 and Theorem 3.1 gives immediately}$ 

$$\mathbb{E}\left[F\left(\frac{1}{T}\sum_{t=1}^{T}\boldsymbol{x}_{t}\right)\right] - \min_{\boldsymbol{x}} F(\boldsymbol{x}) = \mathcal{O}\left(\frac{\ln T}{\lambda T}\right) .$$

However, we can do better! Indeed,  $\ell_t(\boldsymbol{x}) = \frac{\lambda t}{2} \|\boldsymbol{x}\|_2^2 + t \max(1 - y_i \langle \boldsymbol{z}_i, \boldsymbol{x} \rangle, 0)$  or  $\ell_t(\boldsymbol{x}) = \frac{\lambda t}{2} \|\boldsymbol{x}\|_2^2 + t \ln(1 + \exp(-y_i \langle \boldsymbol{z}_i, \boldsymbol{x} \rangle))$  results in  $\lambda t$ -strongly convex loss functions. Using Theorem 4.7, we have that  $\eta_t = \frac{2}{\lambda t(t+1)}$  and Theorem 3.1 gives immediately

$$\mathbb{E}\left[F\left(\frac{2}{T(T+1)}\sum_{t=1}^{T}t\,\boldsymbol{x}_{t}\right)\right]-\min_{\boldsymbol{x}}\;F(\boldsymbol{x})=\mathcal{O}\left(\frac{1}{\lambda T}\right),$$

that is asymptotically better because it does not have the logarithmic term.

## 4.2 Adaptive Algorithms: $L^*$ bounds and AdaGrad

In this section, we will explore a bit more under which conditions we can get better regret upper bounds than  $\mathcal{O}(DL\sqrt{T})$  as  $T\to\infty$ . Also, we will obtain this improved guarantees in an *automatic* way. That is, the algorithm will be *adaptive* to characteristics of the sequence of loss functions, without having to rely on information about the future.

## 4.2.1 Adaptive Learning Rates for Online Subgradient Descent

Consider the minimization of the regret with linear losses:

$$\operatorname{Regret}_T(\boldsymbol{u}) = \sum_{t=1}^T \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle - \sum_{t=1}^T \langle \boldsymbol{g}_t, \boldsymbol{u} \rangle.$$

Using Online Subgradient Descent (OSD), in Chapter 2 we said that the regret for bounded domains can be upper bounded by

$$\sum_{t=1}^T \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle - \sum_{t=1}^T \langle \boldsymbol{g}_t, \boldsymbol{u} \rangle \leq \frac{D^2}{2\eta_T} + \frac{1}{2} \sum_{t=1}^T \eta_t \|\boldsymbol{g}_t\|_2^2 .$$

With a fixed learning rate  $\eta_t = \eta$ , the learning rate that minimizes this upper bound on the regret is

$$\eta^{\star} = \frac{D}{\sqrt{\sum_{t=1}^{T} \|\boldsymbol{g}_t\|_2^2}}.$$

Unfortunately, as we said, this learning rate cannot be used because it assumes the knowledge of the future rounds. However, we might be lucky and we might try to just approximate it in each round using the knowledge up to time t. That is, we might try to use

$$\eta_t = \frac{D}{\sqrt{\sum_{i=1}^t \|g_i\|_2^2}},\tag{4.3}$$

and just skip the rounds in which  $g_i = 0$  to avoid possible divisions by 0. Observe that  $\eta_T = \eta^*$ , so the first term of the regret would be exactly what we need! For the other term, the optimal learning rate would give us

$$\frac{1}{2} \sum_{t=1}^{T} \eta_{T}^{\star} \|\boldsymbol{g}_{t}\|_{2}^{2} = \frac{1}{2} D \sqrt{\sum_{t=1}^{T} \|\boldsymbol{g}_{t}\|_{2}^{2}} \; .$$

Now, let's see what we obtain with our approximation in the other term of the regret:

$$\frac{1}{2} \sum_{t=1}^{T} \eta_t \|\boldsymbol{g}_t\|^2 = \frac{1}{2} D \sum_{t=1}^{T} \frac{\|\boldsymbol{g}_t\|_2^2}{\sqrt{\sum_{i=1}^{t} \|\boldsymbol{g}_i\|_2^2}}.$$

We need a way to upper bound that sum. The way to treat these sums, as we did in other cases, is to try to approximate them with integrals. So, we can use the following very handy Lemma that generalizes a lot of similar specific ones.

**Lemma 4.13.** Let  $a_0 \ge 0$  and  $f: [0, +\infty) \to [0, +\infty)$  a nonincreasing function. Then

$$\sum_{t=1}^{T} a_t f\left(a_0 + \sum_{i=1}^{t} a_i\right) \le \int_{a_0}^{\sum_{t=0}^{T} a_t} f(x) \, \mathrm{d}x.$$

*Proof.* Denote by  $s_t = \sum_{i=0}^t a_i$ 

$$a_t f\left(a_0 + \sum_{i=1}^t a_i\right) = a_t f(s_t) = \int_{s_{t-1}}^{s_t} f(s_t) dx \le \int_{s_{t-1}}^{s_t} f(x) dx$$
.

Summing over  $t = 1, \dots, T$ , we have the stated bound.

Using this Lemma, we have that

$$\frac{1}{2}D\sum_{t=1}^{T} \frac{\|\boldsymbol{g}_{t}\|_{2}^{2}}{\sqrt{\sum_{i=1}^{t} \|\boldsymbol{g}_{i}\|_{2}^{2}}} \leq D\sqrt{\sum_{t=1}^{T} \|\boldsymbol{g}_{t}\|_{2}^{2}}.$$

Surprisingly, this term is only a factor of 2 worse than what we would have got from the optimal choice of  $\eta^*$ . However, this learning rate can be computed without knowledge of the future and it can actually be used! Overall, with this choice we get

$$\operatorname{Regret}_{T}(\boldsymbol{u}) = \sum_{t=1}^{T} \ell_{t}(\boldsymbol{x}_{t}) - \sum_{t=1}^{T} \ell_{t}(\boldsymbol{u}) \leq \frac{3}{2} D \sqrt{\sum_{t=1}^{T} \|\boldsymbol{g}_{t}\|_{2}^{2}}.$$
(4.4)

Note that it is possible to improve the constant in front of the bound to  $\sqrt{2}$  by multiplying the learning rates by  $\frac{\sqrt{2}}{2}$ . So, putting all together we have the following theorem.

**Theorem 4.14.** Let  $V \subset \mathbb{R}^d$  a closed non-empty convex set with diameter D, i.e.,  $\max_{\boldsymbol{x},\boldsymbol{y} \in \mathcal{V}} \|\boldsymbol{x} - \boldsymbol{y}\|_2 \leq D$ . Let  $\ell_1, \dots, \ell_T$  an arbitrary sequence of convex functions  $\ell_t : \mathcal{V} \to \mathbb{R}$  subdifferentiable in  $\mathcal{V}$  for  $t = 1, \dots, T$ . Pick any  $\boldsymbol{x}_1 \in \mathcal{V}$ , and run OSD with  $\eta_t = \frac{\sqrt{2}D}{2\sqrt{\sum_{i=1}^t \|\boldsymbol{g}_i\|_2^2}}$ ,  $t = 1, \dots, T$ , and do not update on rounds when  $\boldsymbol{g}_t = \boldsymbol{0}$ . Then,  $\forall \boldsymbol{u} \in \mathcal{V}$ , the following regret bound holds

$$\operatorname{Regret}_{T}(\boldsymbol{u}) = \sum_{t=1}^{T} (\ell_{t}(\boldsymbol{x}_{t}) - \ell_{t}(\boldsymbol{u})) \leq \sqrt{2}D\sqrt{\sum_{t=1}^{T} \|\boldsymbol{g}_{t}\|_{2}^{2}} = \sqrt{2} \min_{\eta > 0} \frac{D^{2}}{2\eta} + \frac{\eta}{2} \sum_{t=1}^{T} \|\boldsymbol{g}_{t}\|_{2}^{2}.$$

The second equality in the theorem clearly show the advantage of this learning rates: We obtain (almost) the same guarantee we would have got knowing the future gradients!

This is an interesting result on its own: it gives a principled way to set the learning rates with an almost optimal guarantee. Observe that this approach avoid knowing the Lipschitz constants of the functions, so we adapt to it. The downside is that it works only in the bounded case. Another important observation is that the sum of the squared gradients act as an *intrinsic notion of time*, better suited than T to capture the dependency on time.

There are also other consequences of this simple regret upper bound: We will now specialize this result to the case that the losses are *smooth*.

## 4.2.2 Convex Analysis Bits: Dual Norms and Smooth Functions

We now consider a family of loss functions that have the characteristic of being lower bounded by the squared norm of the subgradient. We will also introduce the concept of *dual norms*. While dual norms are not strictly needed for this topic, they give more generality and at the same time they allows me to slowly introduce some of the concepts that will be needed for the chapter on Online Mirror Descent.

**Definition 4.15** (Dual Norm). The **dual norm**  $\|\cdot\|_{\star}$  of a norm  $\|\cdot\|$  is defined as  $\|\theta\|_{\star} = \max_{\boldsymbol{x}:\|\boldsymbol{x}\|<1} \langle \theta, \boldsymbol{x} \rangle$ .

**Example 4.16.** The dual norm of the  $L_2$  norm is the  $L_2$  norm. We can easily prove it. First of all, if  $\theta = 0$ , then the dual norm is 0 too. Hence, let's assume that  $\theta \neq 0$ . Indeed,  $\|\theta\|_{\star} = \max_{\boldsymbol{x}:\|\boldsymbol{x}\|_2 \leq 1} \langle \theta, \boldsymbol{x} \rangle \leq \|\theta\|_2$  by Cauchy-Schwarz inequality. Also, set  $\boldsymbol{v} = \frac{\theta}{\|\theta\|_2}$ , so  $\max_{\boldsymbol{x}:\|\boldsymbol{x}\|_2 \leq 1} \langle \theta, \boldsymbol{x} \rangle \geq \langle \theta, \boldsymbol{v} \rangle = \|\theta\|_2$ .

**Example 4.17.** Let  $p \ge 1$ . The  $L_p$  norm of a vector  $\mathbf{x} \in \mathbb{R}^d$  is defined as  $\|\mathbf{x}\|_p = (\sum_{i=1}^d |x_i|^p)^{1/p}$ . The dual norm is the q-norm where  $\frac{1}{p} + \frac{1}{q} = 1$ . Note that the dual of the  $L_1$  norm is the  $L_\infty$  norm, defined as  $\|\mathbf{x}\|_\infty = \max_{i=1,...,d} |x_i|$ . The proof is left to the reader.

**Example 4.18.** Let A be a positive definite matrix, then it is possible to show that  $\|x\|_A := \sqrt{x^\top Ax}$  is a norm. The dual norm is  $\|x\|_{A^{-1}} = \sqrt{x^\top A^{-1}x}$ . In fact, we have that the dual norm of  $\|\cdot\|_A$  is defined as

$$\begin{split} \|\boldsymbol{\theta}\|_{\star} &= \max_{\boldsymbol{x}: \|\boldsymbol{x}\|_{\boldsymbol{A}} \leq 1} \langle \boldsymbol{\theta}, \boldsymbol{x} \rangle = \max_{\boldsymbol{x}: \boldsymbol{x}^{\top} \boldsymbol{A} \boldsymbol{x} \leq 1} \boldsymbol{\theta}^{\top} \boldsymbol{x} = \max_{\boldsymbol{y}: \boldsymbol{y}^{\top} \boldsymbol{y} \leq 1} \boldsymbol{\theta}^{\top} \boldsymbol{A}^{-1/2} \boldsymbol{y} = \max_{\boldsymbol{y}: \|\boldsymbol{y}\|_{2} \leq 1} (\boldsymbol{A}^{-1/2} \boldsymbol{\theta})^{\top} \boldsymbol{y} = \|\boldsymbol{A}^{-1/2} \boldsymbol{\theta}\|_{2} \\ &= \sqrt{\boldsymbol{\theta}^{\top} \boldsymbol{A}^{-1} \boldsymbol{\theta}}, \end{split}$$

where we have used the change of variable  $y = A^{1/2}x$  in the third equality and the dual norm norm of the  $L_2$  norm from Example 4.16 in the second to last equality.

If you do not know the concept of *operator norms*, the concept of dual norm can be a bit weird at first. One way to understand it is that it is a way to measure how "big" are linear functionals. For example, consider the linear function  $f(x) = \langle z, x \rangle$ , we want to try to understand how big it is. So, we can measure  $\max_{x \neq 0} \frac{\langle z, x \rangle}{\|x\|}$  that is we measure how big is the output of the linear functional compared to its input x, where x is measured with some norm. Now, you can show that the above is equivalent to the dual norm of z.

**Remark 4.19.** The definition of dual norm immediately implies  $\langle \theta, x \rangle \leq \|\theta\|_{\star} \|x\|$ .

Now we can introduce smooth functions, using the dual norms defined above.

**Definition 4.20** (Smooth Function). Let  $f: \mathcal{V} \to \mathbb{R}$  differentiable in an open set containing  $\mathcal{V}$ . We say that f is m-smooth  $w.r.t. \| \cdot \| if \| \nabla f(x) - \nabla f(y) \|_{\star} \le m \|x - y\|$  for all  $x, y \in \mathcal{V}$ .

Keeping in mind the intuition above on dual norms, taking the dual norm of a gradient makes sense if you associate each gradient with the linear functional  $\langle \nabla f(\boldsymbol{y}), \boldsymbol{x} \rangle$ , that is the one needed to create a linear approximation of f.

**Remark 4.21.** *Note that smoothness does not imply convexity.* 

Smooth functions have many properties, for example a smooth function can be upper and lower bounded by a quadratic.

**Lemma 4.22.** Let  $f: \mathcal{V} \to \mathbb{R}$  be m-smooth. Then, for any  $x, y \in \mathcal{V}$ , we have

$$|f(\boldsymbol{y}) - f(\boldsymbol{x}) - \langle \nabla f(\boldsymbol{x}), \boldsymbol{y} - \boldsymbol{x} \rangle| \le \frac{m}{2} \|\boldsymbol{y} - \boldsymbol{x}\|^2$$
.

*Proof.* First, notice that by the definition of smoothness,  $\nabla f: V \to \mathbb{R}^d$  is Lipschitz and so continuous. Hence, by the fundamental theorem of calculus, we have

$$f(\mathbf{y}) = f(\mathbf{x}) + \int_0^1 \langle \nabla f(\mathbf{x} + \tau(\mathbf{y} - \mathbf{x})), \mathbf{y} - \mathbf{x} \rangle d\tau$$

$$= f(\mathbf{x}) + \langle \nabla f(\mathbf{x}), \mathbf{y} - \mathbf{x} \rangle + \int_0^1 \langle \nabla f(\mathbf{x} + \tau(\mathbf{y} - \mathbf{x})) - \nabla f(\mathbf{x}), \mathbf{y} - \mathbf{x} \rangle d\tau.$$

Therefore,

$$|f(\boldsymbol{y}) - f(\boldsymbol{x}) - \langle \nabla f(\boldsymbol{x}), \boldsymbol{y} - \boldsymbol{x} \rangle| = \left| \int_0^1 \langle \nabla f(\boldsymbol{x} + \tau(\boldsymbol{y} - \boldsymbol{x})) - \nabla f(\boldsymbol{x}), \boldsymbol{y} - \boldsymbol{x} \rangle d\tau \right|$$

$$\leq \int_0^1 |\langle \nabla f(\boldsymbol{x} + \tau(\boldsymbol{y} - \boldsymbol{x})) - \nabla f(\boldsymbol{x}), \boldsymbol{y} - \boldsymbol{x} \rangle| d\tau$$

$$\leq \int_0^1 ||\nabla f(\boldsymbol{x} + \tau(\boldsymbol{y} - \boldsymbol{x})) - \nabla f(\boldsymbol{x})||_{\star} ||\boldsymbol{y} - \boldsymbol{x}|| d\tau$$

$$\leq \int_0^1 \tau m ||\boldsymbol{y} - \boldsymbol{x}||^2 d\tau = \frac{m}{2} ||\boldsymbol{y} - \boldsymbol{x}||^2.$$

In the following, we will need the following property.

**Theorem 4.23.** Let  $f: \mathbb{R}^d \to \mathbb{R}$  be m-smooth and bounded from below, then for all  $x \in \mathbb{R}^d$ 

$$\|\nabla f(\boldsymbol{x})\|_{\star}^2 \leq 2m(f(\boldsymbol{x}) - \inf_{\boldsymbol{y} \in \mathbb{R}^d} f(\boldsymbol{y}))$$
.

*Proof.* From Lemma 4.22, for any  $x, v \in \mathbb{R}^d$ , we have

$$\langle -
abla f(oldsymbol{x}), oldsymbol{v}
angle - rac{m}{2} \|oldsymbol{v}\|^2 \leq f(oldsymbol{x}) - f(oldsymbol{x} + oldsymbol{v}) \leq f(oldsymbol{x}) - \inf_{oldsymbol{y} \in \mathbb{R}^d} f(oldsymbol{y}) \;.$$

Given that this holds for any v, we can take the supremum of the left hand side with respect to v. Using Example 6.21, we have

$$\frac{1}{2m} \|\nabla f(\boldsymbol{x})\|_{\star}^{2} = \sup_{\boldsymbol{v}} \langle -\nabla f(\boldsymbol{x}), \boldsymbol{v} \rangle - \frac{m}{2} \|\boldsymbol{v}\|^{2} \le f(\boldsymbol{x}) - \inf_{\boldsymbol{y} \in \mathbb{R}^{d}} f(\boldsymbol{y}).$$

#### 4.2.3 $L^*$ bounds

We now introduce the  $L^*$  bounds, that depend on the cumulative competitor loss that is usually denoted by  $L^*$ .

Assume now that the loss functions  $\ell_1, \dots, \ell_T$  are bounded from below and M-smooth on an open sets that includes  $\mathcal{V}$ . Without loss of generality, we can assume that each of them is bounded from below by 0. Under these assumptions, we can obtain bounds that depends on the cumulative loss of the competitor rather than time.

From the regret of OGD in Theorem 2.13 and Theorem 4.23 for a constant learning rate  $\eta$ , we obtain for any  $u \in \mathcal{V}$ 

$$\sum_{t=1}^{T} (\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) \leq \frac{\|\boldsymbol{u} - \boldsymbol{x}_1\|_2^2}{2\eta} + \eta \sum_{t=1}^{T} m\ell_t(\boldsymbol{x}_t),$$

that reordering implies

$$\sum_{t=1}^{T} (\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) \leq \frac{\eta m}{1 - \eta m} \sum_{t=1}^{T} \ell_t(\boldsymbol{u}) + \frac{\|\boldsymbol{u} - \boldsymbol{x}_1\|_2^2}{2\eta(1 - \eta m)}$$

Assuming  $\eta \leq \frac{1}{2m}$ , we simplify this regret upper bound in

$$\sum_{t=1}^{T} (\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) \le 2\eta m \sum_{t=1}^{T} \ell_t(\boldsymbol{u}) + \frac{\|\boldsymbol{u} - \boldsymbol{x}_1\|_2^2}{\eta}.$$

This is already an interesting result because it guarantees that a fixed learning rate that depends only on m can achieve a vanishing average regret if there exists a competitor  $u \in \mathcal{V}$  whose cumulative loss grows sublinearly. However, we could do better. In fact, for a fixed  $u \in \mathcal{V}$ , setting  $\eta = \min\left(\frac{1}{\sqrt{2m\sum_{t=1}^T \ell_t(u)}}, \frac{1}{2m}\right)$ , we obtain

$$\sum_{t=1}^{T} (\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) \le (\|\boldsymbol{u} - \boldsymbol{x}_1\|_2^2 + 1) \max \left( \sqrt{2m \sum_{t=1}^{T} \ell_t(\boldsymbol{u})}, 2m \right) .$$

Comparing this bound to the one of OGD with Lipschitz losses, we see that here the dependency is on  $\sqrt{\sum_{t=1}^T \ell_t(u)}$  instead of  $\sqrt{T}$ . The cumulative loss of the competitor can be much smaller than T and in particular can be even 0. In this case, the regret is upper bounded by a constant. Moreover, in this latter case we can afford to use a learning rate  $\eta$  that depends only on the smoothness constant. However, this result is partially interesting because it requires the knowledge of the future through the cumulative loss of the competitor. In the following, we show how to easily get rid of this limitation with a different choice of the learning rate.

In fact, under the same assumptions on the losses, from the regret in Theorem 4.14 and Theorem 4.23 we immediately obtain

$$\operatorname{Regret}_{T}(\boldsymbol{u}) = \sum_{t=1}^{T} \ell_{t}(\boldsymbol{x}_{t}) - \sum_{t=1}^{T} \ell_{t}(\boldsymbol{u}) \leq 2D \sqrt{m \sum_{t=1}^{T} \ell_{t}(\boldsymbol{x}_{t})},$$

where D is the diameter of  $\mathcal{V}$ , assumed to be bounded. This is an implicit bound, in the sense that  $\sum_{t=1}^{T} \ell_t(x_t)$  appears on both sides of the inequality. To makes it explicit, we will use the following simple Lemma (proof left as an exercise).

**Lemma 4.24.** Let a, c > 0,  $b \ge 0$ , and  $x \ge 0$  such that  $x - \sqrt{ax + b} \le c$ . Then  $x \le a + c + 2\sqrt{b + ac}$ .

So, we have the following theorem.

**Theorem 4.25.** Let  $V \subset \mathbb{R}^d$  a closed non-empty convex set with diameter D, i.e.,  $\max_{\boldsymbol{x},\boldsymbol{y} \in V} \|\boldsymbol{x} - \boldsymbol{y}\|_2 \leq D$ . Let  $\ell_1, \dots, \ell_T$  an arbitrary sequence of non-negative convex functions  $\ell_t : V \to \mathbb{R}$  m-smooth in open sets containing V for  $t = 1, \dots, T$ . Pick any  $\boldsymbol{x}_1 \in V$ , run OGD with  $\eta_t = \frac{\sqrt{2}D}{2\sqrt{\sum_{i=1}^t \|\boldsymbol{g}_i\|_2^2}}$ ,  $t = 1, \dots, T$ , and do not update on rounds in which  $\boldsymbol{g}_t = \boldsymbol{0}$ . Then,  $\forall \boldsymbol{u} \in V$ , the following regret bound holds

$$\operatorname{Regret}_{T}(\boldsymbol{u}) = \sum_{t=1}^{T} \ell_{t}(\boldsymbol{x}_{t}) - \sum_{t=1}^{T} \ell_{t}(\boldsymbol{u}) \leq 4mD^{2} + 4D\sqrt{m\sum_{t=1}^{T} \ell_{t}(\boldsymbol{u})}.$$

This regret guarantee is very interesting because in the worst case it is still of the order  $\mathcal{O}(\sqrt{T})$ , but in the best case scenario it becomes a constant! In fact, if there exists a  $u \in \mathcal{V}$  such that  $\sum_{t=1}^{T} \ell_t(u) = 0$  we get a constant regret. Basically, if the losses are "easy", the algorithm *adapts* to this situation and gives us a better regret.

#### 4.2.4 AdaGrad

We now present another application of the regret bound in (4.4). **AdaGrad**, that stands for Adaptive Gradient, is an OCO algorithm proposed independently by McMahan and Streeter [2010] and Duchi et al. [2010]. It aims at being adaptive to the sequence of gradients. It is usually known as a stochastic optimization algorithm, but in reality it was proposed for the online setting. To use it as a stochastic algorithm, you should use an online-to-batch conversion, otherwise you do not have any guarantee of convergence.

We will present a proof that only allows hyperrectangles as feasible sets V, on the other hand the restriction makes the proof almost trivial. Let's see how it works.

AdaGrad has key ingredients:

- A coordinate-wise learning process;
- The adaptive learning rates in (4.3).

For the first ingredient, as we said, the regret of any OCO problem can be upper bounded by the regret of the Online Linear Optimization (OLO) problem. That is,

$$\sum_{t=1}^T \ell_t(\boldsymbol{x}_t) - \sum_{t=1}^T \ell_t(\boldsymbol{u}) \leq \sum_{t=1}^T \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle - \sum_{t=1}^T \langle \boldsymbol{g}_t, \boldsymbol{u} \rangle .$$

Now, the essential observation is to explicitly write the inner product as a sum of product over the single coordinates:

$$\sum_{t=1}^{T} \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle - \sum_{t=1}^{T} \langle \boldsymbol{g}_t, \boldsymbol{u} \rangle = \sum_{t=1}^{T} \sum_{i=1}^{d} g_{t,i} x_{t,i} - \sum_{t=1}^{T} \sum_{i=1}^{d} g_{t,i} u_i = \sum_{i=1}^{d} \left( \sum_{t=1}^{T} g_{t,i} x_{t,i} - \sum_{t=1}^{T} g_{t,i} u_i \right) = \sum_{i=1}^{d} \operatorname{Regret}_{T,i}(u_i),$$

where we denoted by  $\operatorname{Regret}_{T,i}(u_i)$  the regret of the 1-dimensional OLO problem over coordinate i, that is  $\sum_{t=1}^{T} g_{t,i} x_{t,i} - \sum_{t=1}^{T} g_{t,i} u_i$ . In words, we can decompose the original regret as the sum of d OLO regret minimization problems and we can try to focus on each one of them separately.

A good candidate for the 1-dimensional problems is OSD with the learning rates in (4.3). We can specialize the regret in (4.4) to the 1-dimensional case for linear losses, so we get for each coordinate i

$$\sum_{t=1}^{T} g_{t,i} x_{t,i} - \sum_{t=1}^{T} g_{t,i} u_i \le \sqrt{2} D_i \sqrt{\sum_{t=1}^{T} g_{t,i}^2}.$$

This choice gives us the AdaGrad algorithm in Algorithm 4.1.

#### Algorithm 4.1 AdaGrad for Hyperrectangles

```
Require: V = \{x : a_i \le x_i \le b_i\}, x_1 \in V
  1: for t = 1 to T do
            Pay \ell_t({m x}_t) for a \ell_t: {\mathcal V} 	o {\mathbb R} subdifferentiable in {\mathcal V}
  3:
            Set \boldsymbol{g}_t \in \partial \ell_t(\boldsymbol{x}_t)
            for i=1 to d do
                 if g_{t,i} \neq 0 then
  6:
                     \begin{split} \text{Set } \eta_{t,i} &= \frac{\sqrt{2}D_i}{2\sqrt{\sum_{j=1}^t g_{j,i}^2}} \\ x_{t+1,i} &= \max(\min(x_{t,i} - \eta_{t,i}g_{t,i}, b_i), a_i) \end{split}
  7:
  8:
  9:
 10:
                      x_{t+1,i} = x_{t,i}
                 end if
 11:
 12:
            end for
 13: end for
```

Putting all together, we have immediately the following regret guarantee.

**Theorem 4.26.** Let  $V = \{x : a_i \leq x_i \leq b_i\}$  with diameters along each coordinate equal to  $D_i = b_i - a_i$ . Let  $\ell_1, \dots, \ell_T$  an arbitrary sequence of convex functions  $\ell_t : V \to \mathbb{R}$  subdifferentiable in V for  $t = 1, \dots, T$ . Pick any  $x_1 \in V$  and  $\eta_{t,i} = \frac{\sqrt{2}D_i}{2\sqrt{\sum_{j=1}^t g_{j,i}^2}}, t = 1, \dots, T$ . Then,  $\forall u \in V$ , Algorithm 4.1 guarantees

$$\operatorname{Regret}_{T}(\boldsymbol{u}) = \sum_{t=1}^{T} \ell_{t}(\boldsymbol{x}_{t}) - \sum_{t=1}^{T} \ell_{t}(\boldsymbol{u}) \leq \sqrt{2} \sum_{i=1}^{d} D_{i} \sqrt{\sum_{t=1}^{T} g_{t,i}^{2}}.$$

Is this a better regret bound compared to the one in Theorem 4.14? It depends! To compare the two, let's first consider the case that V is a hyperrectangle. Then, we have to compare

$$D\sqrt{\sum_{t=1}^T \|\boldsymbol{g}_t\|_2^2} \qquad \qquad \text{versus} \qquad \qquad \sum_{i=1}^d D_i \sqrt{\sum_{t=1}^T g_{t,i}^2} \; .$$

From Cauchy-Schwarz, we have that  $\sum_{i=1}^{d} D_i \sqrt{\sum_{t=1}^{T} g_{t,i}^2} \le D \sqrt{\sum_{t=1}^{T} \|\boldsymbol{g}_t\|_2^2}$ . So, assuming the same sequence of subgradients, AdaGrad has never a worse regret on hyperrectangles. For a more precise quantification of the gain of

AdaGrad, let's now assume that  $\mathcal{V}$  is a hypersquare. Also, note that

$$\sqrt{\sum_{t=1}^{T} \|\boldsymbol{g}_{t}\|_{2}^{2}} \leq \sum_{i=1}^{d} \sqrt{\sum_{t=1}^{T} g_{t,i}^{2}} \leq \sqrt{d} \sqrt{\sum_{t=1}^{T} \|\boldsymbol{g}_{t}\|_{2}^{2}}, \tag{4.5}$$

where the lower bound is by the fact that the  $L_1$  norm is bigger than the  $L_2$ , and the upper bound is given by Cauchy-Schwarz. So, in the case that  $\mathcal{V}$  is a hypercube we have  $D_i = D_{\infty} = \max_{\boldsymbol{x},\boldsymbol{y}} \|\boldsymbol{x} - \boldsymbol{y}\|_{\infty}$  and  $D = \sqrt{d}D_{\infty}$ , the bound of AdaGrad is between  $1/\sqrt{d}$  and 1 times the bound of Theorem 4.14. In other words, if we are lucky with the subgradients, we might save us a factor of  $\sqrt{d}$  in the guarantee.

However, what does happen if the domain is a  $L_2$  ball? First of all, it is possible to generalize AdaGrad to work on  $L_2$  balls and the guarantee remains the same. Hence, in this case, we have  $D_i = D_{\infty} = D$ , so from (4.5), we have

$$\frac{1}{\sqrt{d}} \sum_{i=1}^d D_i \sqrt{\sum_{t=1}^T g_{t,i}^2} \leq D \sqrt{\sum_{t=1}^T \|\boldsymbol{g}_t\|_2^2} \leq \sum_{i=1}^d D_i \sqrt{\sum_{t=1}^T g_{t,i}^2} \; .$$

Hence, for an  $L_2$  ball the opposite happens: the bound in Theorem 4.14 is never worse than the one of AdaGrad and, depending on the subgradients, we can gain a  $\sqrt{d}$  factor. Overall, the **shape of the domain** determines the potential gain of one approach over the other and the specific sequence of subgradients determines the actual gain. It is possible to show that hyperrectangles are indeed the best domains for AdaGrad. We will explore this issue of choosing the online algorithm based on the shape of the feasible set  $\mathcal V$  when we will introduce Online Mirror Descent in Chapter 6.

Another big advantage of AdaGrad is the property of being coordinate-wise *scale-free*. That is, if each coordinate of the gradients are multiplied by different constants, the learning rate will automatically scale them back. This fact is not immediately apparent from the regret because by scaling the coordinate of the gradients the optimal solution  $\boldsymbol{u}$  would also scale accordingly, but the fixed diameters of the feasible set hide it. This might be useful in the case the ranges of coordinates of the gradients are vastly different one from the other. Indeed, this does happen in many machine learning problems, for example, in the stochastic optimization of deep neural networks, where the first layers have smaller magnitude of the gradients compared to the last layers.

## 4.3 History Bits

The concept of strong convexity is defined for the first time in Polyak [1966].

The logarithmic regret in Corollary 4.9 was shown for the first time in the seminal paper Hazan et al. [2006, 2007]. The general statement in Theorem 4.7 was proven by Hazan et al. [2008].

The non-uniform averaging for the online-to-batch conversion of Example 4.12 is from Lacoste-Julien et al. [2012], but there it is not proposed as an online-to-batch conversion. The basic idea of solving the problem of SVM with OSD and online-to-batch conversion of Example 4.12 was the Pegasos algorithm [Shalev-Shwartz et al., 2007], for many years the most used optimizer for SVMs.

The adaptive learning rate in (4.3) first appeared in Streeter and McMahan [2010]. However, similar methods were used long time before. Indeed, the key observation to approximate oracle quantities with estimates up to time t was first proposed in the self-confident algorithms [Auer et al., 2002c], where the learning rate is inversely proportional to the square root of the cumulative loss of the algorithm, and for smooth losses it implies the  $L^*$  bounds similar to the one in Theorem 4.25. The  $L^*$  bound for the square loss and linear predictors was introduced by Cesa-Bianchi et al. [1996]. In the past, several work focused on obtaining regret upper bounds depending on constant times  $L^*$  [see, e.g., Kivinen and Warmuth, 1997], however these guarantees are meaningful only if  $L^*$  is sublinear in T. Zhang [2004] explored the use of  $L^*$  bounds in stochastic optimization. The observation that the cumulative sum of the squared gradients act as an intrinsic notion of time comes from the statistics literature, see the discussion in Blackwell and Freedman [1973].

AdaGrad was proposed in basically identically form independently by two groups at the same conference: McMahan and Streeter [2010] and Duchi et al. [2010]. The analysis presented here is the one in Streeter and McMahan [2010] that does not handle generic feasible sets and does not support the "full-matrices" proposed in Duchi et al.

[2010], i.e., full-matrix learning rates instead of diagonal ones. However, in machine learning applications AdaGrad is rarely used with a projection step (even if doing so provably destroys the worst-case performance [Orabona and Pál, 2018]). Also, in the adversarial setting full-matrices do not seem to offer advantages in terms of regret compared to diagonal ones, see the discussion in Cutkosky [2020b, Section 5].

Note that the AdaGrad learning rate is usually written as

$$\eta_{t,i} = \frac{D_i}{\epsilon + \sqrt{\sum_{j=1}^t g_{j,i}^2}},$$

where  $\epsilon > 0$  is a small constant used to prevent division by zero. In reality,  $\epsilon$  is not necessary: there should be no update when the coordinate of the gradient is 0 [Orabona and Pál, 2015, 2018, Agarwal et al., 2020]. Moreover, removing  $\epsilon$  makes the updates scale-free, as stressed in Orabona and Pál [2015, 2018]. Scale-freeness in online learning has been introduced in Cesa-Bianchi et al. [2005, 2007] for the setting of learning with expert advice and in Orabona and Pál [2015, 2018] for OCO.

AdaGrad inspired an incredible number of clones, most of them with similar, worse, or no regret guarantees. The keyword "adaptive" itself has shifted its meaning over time. It used to denote the ability of the algorithm to obtain the same guarantee as it knew in advance a particular property of the data (i.e., adaptive to the gradients/noise/scale = (almost) same performance as it knew the gradients/noise/scale in advance). Indeed, in Statistics this keyword is used with the same meaning. However, "adaptive" has changed its meaning over time. Nowadays, it seems to denote any kind of coordinate-wise learning rates that does not guarantee anything in particular.

## 4.4 Exercises

**Problem 4.1.** Prove that OSD in Example 4.11 with  $x_1 = 0$  is exactly the Follow-the-Leader strategy for that particular problem.

**Problem 4.2.** Prove that  $\ell_t(x) = ||x - z_t||_2^2$  is 2-strongly convex w.r.t.  $||\cdot||_2$  and derive the OSD update for it and its regret guarantee.

**Problem 4.3.** Prove that  $f(x) = \frac{1}{2} ||x||_p^2$  is p-1-strongly convex w.r.t.  $||\cdot||_p$  where  $1 \le p \le 2$ .

**Problem 4.4.** Prove that the dual norm of  $\|\cdot\|_p$  is  $\|\cdot\|_q$ , where  $\frac{1}{p} + \frac{1}{q} = 1$  and  $p, q \ge 1$ .

**Problem 4.5.** Show that using online subgradient descent on a bounded domain V with the learning rates  $\eta_t = \mathcal{O}(1/t)$  with Lipschitz, smooth, and strongly convex functions you can get  $\mathcal{O}(\ln(1+L^*))$  bounds.

**Problem 4.6.** Prove that the logistic loss  $\ell(\boldsymbol{x}) = \ln(1 + \exp(-y\langle \boldsymbol{z}, \boldsymbol{x}\rangle))$ , where  $\|\boldsymbol{z}\|_2 \le 1$  and  $y \in \{-1, 1\}$  is  $\frac{1}{4}$ -smooth w.r.t.  $\|\cdot\|_2$ .

## **Chapter 5**

# **Lower bounds for Online Linear Optimization**

In this chapter we will present some lower bounds for online linear optimization (OLO). Remembering that linear losses are convex, this immediately gives us lower bounds for online convex optimization (OCO). We will consider both the constrained and the unconstrained case. The lower bounds are important because they inform us on what are the optimal algorithms and where are the gaps in our knowledge.

## 5.1 Lower Bounds for Bounded OLO

We will first consider the bounded constrained case. Finding a lower bound accounts to find a strategy for the adversary that forces a certain regret onto the algorithm, *no matter what the algorithm does*. We will use the probabilistic method to construct our lower bound.

The basic method relies on the fact that if for a given  $K \in \mathbb{R}$  I can construct a sequence of random vectors  $\tilde{g}_1, \dots, \tilde{g}_T$  such that

$$\mathbb{E}\left[\sum_{t=1}^T \langle ilde{m{g}}_t, m{x}_t 
angle
ight] \geq K,$$

this implies that there exists a sequence  $g_1, \ldots, g_T$  among all the possible random sequences such that

$$\sum_{t=1}^T \langle oldsymbol{g}_t, oldsymbol{x}_t 
angle \geq K$$
 .

It is easy to convice oneself that this is true: if for *all* sequences we would have  $\sum_{t=1}^{T} \langle \tilde{g}_t, x_t \rangle < K$ , then the expectation should also be strictly less than K, contradicting our assumption.

For us, it means that we prove the existence of "difficult" sequence of functions through a result on the expectation with respect to a distribution over stochastic functions. Why do you rely on expectations rather than actually constructing an adversarial sequence? Because the use of stochastic loss functions makes very easy to deal with arbitrary algorithms. In particular, we will choose a distribution over stochastic loss functions that makes the expected loss of the algorithm equal to 0, independently from the strategy of the algorithm.

**Theorem 5.1.** Let  $V \subset \mathbb{R}^d$  be any non-empty bounded closed convex subset. Let  $D = \sup_{\boldsymbol{v}, \boldsymbol{w} \in \mathcal{V}} \|\boldsymbol{v} - \boldsymbol{w}\|_2$  be the diameter of V. Let A be any (possibly randomized) algorithm for OLO on V. Let T be any non-negative integer. Then, there exists a sequence of vectors  $\boldsymbol{g}_1, \ldots, \boldsymbol{g}_T$  with  $\|\boldsymbol{g}_t\|_2 \leq L$  and  $\boldsymbol{u} \in V$  such that the regret of algorithm A satisfies

$$\operatorname{Regret}_T(\boldsymbol{u}) = \sum_{t=1}^T \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle - \sum_{t=1}^T \langle \boldsymbol{g}_t, \boldsymbol{u} \rangle \ge \frac{\sqrt{2}LD\sqrt{T}}{4}.$$

*Proof.* Let's denote by  $\operatorname{Regret}_T = \max_{\boldsymbol{u} \in \mathcal{V}} \operatorname{Regret}_T(\boldsymbol{u})$ . Let  $\boldsymbol{v}, \boldsymbol{w} \in \mathcal{V}$  such that  $\|\boldsymbol{v} - \boldsymbol{w}\|_2 = D$ . Let  $\boldsymbol{z} = \frac{\boldsymbol{v} - \boldsymbol{w}}{\|\boldsymbol{v} - \boldsymbol{w}\|_2}$ , so that  $\langle \boldsymbol{z}, \boldsymbol{v} - \boldsymbol{w} \rangle = D$ . Let  $\epsilon_1, \dots, \epsilon_T$  be i.i.d. Rademacher random variables, that is  $\mathbb{P}\{\epsilon_t = 1\} = \mathbb{P}\{\epsilon_t = -1\} = 1/2$  and set the vector of the stochastic linear losses  $\tilde{\boldsymbol{g}}_t = L\epsilon_t \boldsymbol{z}$ .

So, we have

$$\mathbb{E}_{\tilde{\boldsymbol{g}}_{1},...,\tilde{\boldsymbol{g}}_{T}} \left[ \sum_{t=1}^{T} \langle \tilde{\boldsymbol{g}}_{t}, \boldsymbol{x}_{t} \rangle - \min_{\boldsymbol{u} \in \mathcal{V}} \sum_{t=1}^{T} \langle \tilde{\boldsymbol{g}}_{t}, \boldsymbol{u} \rangle \right]$$

$$= \mathbb{E}_{\epsilon_{1},...,\epsilon_{T}} \left[ \sum_{t=1}^{T} L \epsilon_{t} \langle \boldsymbol{z}, \boldsymbol{x}_{t} \rangle - \min_{\boldsymbol{u} \in \mathcal{V}} \sum_{t=1}^{T} L \epsilon_{t} \langle \boldsymbol{z}, \boldsymbol{u} \rangle \right] = \mathbb{E}_{\epsilon_{1},...,\epsilon_{T}} \left[ -\min_{\boldsymbol{u} \in \mathcal{V}} \sum_{t=1}^{T} L \epsilon_{t} \langle \boldsymbol{z}, \boldsymbol{u} \rangle \right]$$

$$= \mathbb{E}_{\epsilon_{1},...,\epsilon_{T}} \left[ \max_{\boldsymbol{u} \in \mathcal{V}} \sum_{t=1}^{T} -L \epsilon_{t} \langle \boldsymbol{z}, \boldsymbol{u} \rangle \right] = \mathbb{E}_{\epsilon_{1},...,\epsilon_{T}} \left[ \max_{\boldsymbol{u} \in \mathcal{V}} \sum_{t=1}^{T} L \epsilon_{t} \langle \boldsymbol{z}, \boldsymbol{u} \rangle \right]$$

$$\geq \mathbb{E}_{\epsilon_{1},...,\epsilon_{T}} \left[ \max_{\boldsymbol{u} \in \{\boldsymbol{v},\boldsymbol{w}\}} \sum_{t=1}^{T} L \epsilon_{t} \langle \boldsymbol{z}, \boldsymbol{u} \rangle \right] = \mathbb{E}_{\epsilon_{1},...,\epsilon_{T}} \left[ \frac{1}{2} \sum_{t=1}^{T} L \epsilon_{t} \langle \boldsymbol{z}, \boldsymbol{v} + \boldsymbol{w} \rangle + \frac{1}{2} \left| \sum_{t=1}^{T} L \epsilon_{t} \langle \boldsymbol{z}, \boldsymbol{v} - \boldsymbol{w} \rangle \right| \right]$$

$$= \frac{L}{2} \mathbb{E}_{\epsilon_{1},...,\epsilon_{T}} \left[ \left| \sum_{t=1}^{T} \epsilon_{t} \langle \boldsymbol{z}, \boldsymbol{v} - \boldsymbol{w} \rangle \right| \right] = \frac{LD}{2} \mathbb{E}_{\epsilon_{1},...,\epsilon_{T}} \left[ \left| \sum_{t=1}^{T} \epsilon_{t} \right| \right] \geq \frac{\sqrt{2}LD\sqrt{T}}{4}.$$

where in the first equality we used  $\mathbb{E}[\epsilon_t] = 0$  and the independence of  $\epsilon_t$  and  $x_t$ , the fact that  $\epsilon_t$  and  $-\epsilon_t$  follow the same distribution in the fourth equality,  $\max(a,b) = \frac{a+b}{2} + \frac{|a-b|}{2}$  in the fifth equality, and Khintchine inequality (Theorem B.1) in the last inequality.

Now, given that the expectation is lower bound by a positive constant, there exists a sequence of realizations of the random variables that gives the same lower bound.  $\Box$ 

**Remark 5.2.** Differently from similar proofs, in the above proof we do not assume that V is symmetric with respect to  $\mathbf{0}$ .

We see that the lower bound is a constant multiplicative factor from the upper bound we proved for Online Subgradient Descent (OSD) with learning rates  $\eta_t = \frac{D}{L\sqrt{t}}$  or  $\eta = \frac{D}{L\sqrt{T}}$ . This means that OSD is asymptotically optimal with both settings of the learning rate.

At this point there is an important consideration to do: How can this be the optimal regret when we managed to prove a better regret, for example, with adaptive learning rates in Section 4.2? The subtlety is that, constraining the adversary to play L-Lipschitz losses, the adversary could always force on the algorithm at least the regret in Theorem 5.1. However, we can design algorithms that take advantage of *suboptimal plays of the adversary*. Indeed, for example, if the adversary plays in a way that all the subgradients have the same norm equal to L, there is nothing to adapt to!

## **5.2** Lower Bounds for Unconstrained OLO

The previous lower bound applies only to the constrained setting. In the unconstrained setting, we proved that OSD with  $x_1=\mathbf{0}$  and constant learning rate of  $\eta=\frac{1}{L\sqrt{T}}$  gives a regret of  $\frac{1}{2}L(\|\boldsymbol{u}\|_2^2+1)\sqrt{T}$  for any  $\boldsymbol{u}\in\mathbb{R}^d$ . Is this regret optimal? It is clear that the regret must be at least linear in  $\|\boldsymbol{u}\|_2$ . In fact, we could select a specific  $\boldsymbol{u}$ , pass the information of  $\|\boldsymbol{u}\|_2$  to the online learning algorithm and make the problem constrained in  $\mathcal{V}=\{\boldsymbol{x}:\|\boldsymbol{x}\|_2\leq\|\boldsymbol{u}\|_2\}$ , so that the lower bound for bounded OLO would hold. However, we now show that the correct dependency in  $\|\boldsymbol{u}\|_2$  is more than linear, so the unconstrained setting is strictly more difficult than the bounded one.

The approach I will follow is to *reduce the OLO game to the online game of betting on a coin*, where the lower bounds are easier to prove. So, let's introduce the coin-betting online game:

- Start with an initial amount of money  $\epsilon > 0$ .
- In each round, the algorithm bets a fraction of its current wealth on the outcome of a coin.

• The outcome of the coin is revealed and the algorithm wins or loses its bet, 1 to 1.

The aim of this online game is to win as much money as possible. Also, as in all the online games we consider, we do not assume anything on how the outcomes of the coin are decided. Note that this game can also be written as OCO using the log loss.

We will denote by  $c_t \in \{-1,1\}, t=1,\ldots,T$  the outcomes of the coin. We will use the absolute value of  $\beta_t \in [-1,1]$  to denote the fraction of money to bet and its sign to denote on which side we are betting. The money the algorithm has won from the beginning of the game till the end of round t will be denoted by  $r_t$  and given that the money are won or lost 1 to 1, we have

Money at the end of round 
$$t$$
 Money at the beginning of round  $t$  Money won or lost 
$$\overbrace{r_{t}+\epsilon} = \overbrace{r_{t-1}+\epsilon} + \overbrace{c_{t}\beta_{t}(r_{t-1}+\epsilon)} = \epsilon \prod_{i=1}^{t} (1+\beta_{i}c_{i}),$$

where we used the fact that  $r_0 = 0$ . We will also denote by  $x_t = \beta_t(\epsilon + r_{t-1})$  the bet of the algorithm on round t.

If we got all the outcomes of the coin correct, we would double our money in each round, so that  $\epsilon + r_T = \epsilon 2^T$ . On the other hand, if the adversary can always select a coin outcome that is the opposite of our bet. Hence, we are interested in the best any algorithm can do when the adversary is constrained to give us a sequence of coins where one side is appearing more often the other one.

To facilitate the use of this theorem in the next pages, we will also slightly generalize the problem assuming that the coins are in  $\{-L, L\}$  instead of  $\{-1, 1\}$ , where L > 0.

**Theorem 5.3.** Let  $T \ge 1$  and  $0 \le q \le \frac{T}{2}$ . Then, for any online betting algorithm that guarantees non-negative wealth on any sequence of coins T in  $\{-L, L\}$  and starts with initial wealth  $\epsilon$ , there exists a sequence of coins such that  $|\sum_{t=1}^{T} c_t| \ge 2qL$  and the wealth of the algorithm is upper bounded by

$$\frac{3}{2} \left( \frac{2q}{\sqrt{T}} + 1 \right) \epsilon \exp\left( T \cdot D\left( \frac{1}{2} + \frac{q}{T} \middle\| \frac{1}{2} \right) \right) \le \frac{3}{2} \left( \frac{2q}{\sqrt{T}} + 1 \right) \epsilon \exp\left( 2\frac{q^2}{T} + 3.1\frac{q^4}{T^3} \right),$$

where D(p||q) denotes the KL divergence between two Bernoulli distributions with parameters p and q:

$$D(p||q) = p \ln \left(\frac{p}{q}\right) + (1-p) \ln \left(\frac{1-p}{1-q}\right) .$$

*Proof.* Let  $Y_t$  independent random variable that assume the value of 1 with probability 0.5 and -1 with probability 0.5. Hence, we have that  $\mathbb{E}[\sum_{t=1}^T x_t L Y_t] = 0$ , and also  $\sum_{t=1}^T x_t L Y_t \ge -\epsilon$  for the hypothesis on the betting algorithm. For any q > 0, it follows that

$$0 = \mathbb{E}\left[\sum_{t=1}^{T} x_{t} Y_{t}\right]$$

$$= \mathbb{E}\left[\sum_{t=1}^{T} x_{t} Y_{t} \middle| \sum_{t=1}^{T} Y_{t} \middle| < 2q\right] \mathbb{P}\left\{\left|\sum_{t=1}^{T} Y_{t} \middle| < 2q\right\} + \mathbb{E}\left[\sum_{t=1}^{T} x_{t} Y_{t} \middle| \sum_{t=1}^{T} Y_{t} \middle| \geq 2q\right] \mathbb{P}\left\{\left|\sum_{t=1}^{T} Y_{t} \middle| \geq 2q\right\}\right\}$$

$$\geq -\frac{\epsilon}{L} + \left(\frac{\epsilon}{L} + \mathbb{E}\left[\sum_{t=1}^{T} x_{t} Y_{t} \middle| \sum_{t=1}^{T} Y_{t} \middle| \geq 2q\right]\right) P\left\{\left|\sum_{t=1}^{T} Y_{t} \middle| \geq 2q\right\}\right\},$$

hence

$$\mathbb{E}\left[\sum_{t=1}^{T} x_t Y_t \middle| \left| \sum_{t=1}^{T} Y_t \middle| \ge 2q \right] \le \frac{\epsilon}{L\mathbb{P}\left\{ \left| \sum_{t=1}^{T} Y_t \middle| \ge 2q \right\} - \frac{\epsilon}{L}} = \frac{\epsilon}{2L\mathbb{P}\left\{ \sum_{t=1}^{T} Y_t \ge 2q \right\} - \frac{\epsilon}{L}} \right].$$

Using the fact that  $\mathbb{P}\left\{\sum_{t=1}^{T} Y_t \geq 2q\right\} = \mathbb{P}\left\{\sum_{t=1}^{T} \frac{Y_t + 1}{2} \geq \frac{1}{2}T + q\right\}$ , where  $\frac{Y_t + 1}{2}$  are Bernoulli random variables, we can apply Lemma D.3, to obtain

$$\mathbb{P}\left\{\sum_{t=1}^{T} Y_t \ge 2q\right\} \ge \frac{1}{3} \frac{1}{\frac{2q}{\sqrt{T}} + 1} \exp\left(-T \cdot D\left(\frac{1}{2} + \frac{q}{T} \left\|\frac{1}{2}\right)\right) \ .$$

Hence, we have

$$\mathbb{E}\left[\sum_{t=1}^T x_t L Y_t \middle| \left|\sum_{t=1}^T Y_t \middle| \ge 2q\right| \le \frac{3}{2} \epsilon \left(\frac{2q}{\sqrt{T}} + 1\right) \exp\left(T \cdot D\left(\frac{1}{2} + \frac{q}{T} \middle\| \frac{1}{2}\right)\right) - \epsilon \right].$$

Given that the minimum over a set is smaller than or equal to the expectation with respect to any distribution over the set, there exists a sequence of  $c_1, \ldots, c_T \in \{-L, L\}^T$  such that  $\frac{1}{L} |\sum_{t=1}^T c_t| \ge 2q$  and the wealth of the algorithm is deterministically upper bounded by

$$\frac{3}{2}\epsilon \left(\frac{2q}{\sqrt{T}} + 1\right) \exp\left(T \cdot D\left(\frac{1}{2} + \frac{q}{T} \middle\| \frac{1}{2}\right)\right) \ .$$

For the second upper bound, it is enough to use the elementary inequality

$$D\left(\frac{1}{2} + x \middle| \frac{1}{2}\right) \le 2x^2 + 3.1x^4, \quad |x| \le \frac{1}{2}.$$

**Remark 5.4.** It is also possible to upper bound the left hand side of the bound in the previous Theorem with the wealth of the best constant betting fraction.

For the expression of the optimal wealth on the  $c_1,\ldots,c_T$ , consider the wealth of strategy that bets a constant amount of money  $\beta$ . Starting with initial money  $\epsilon$ , after T rounds the wealth is  $\epsilon \prod_{t=1}^T (1+\beta c_t)$ . By taking the derivative of the logarithm of the wealth, it is immediate to verify that the  $\beta^*$  that maximizes the above quantity is  $\frac{\sum_{t=1}^T c_t}{L^2 T}$ . Denote by  $k = |\{c_t : c_t = L\}|$ , hence we have  $\beta^* = \frac{2k-T}{L^2 T}$ . Hence, the optimal wealth is

$$\epsilon (1+\beta^{\star}L)^k (1-\beta^{\star}L)^{T-k} = \epsilon \exp\left(k\ln 2\frac{k}{T} + (T-k)\ln 2\left(1-\frac{k}{T}\right)\right) = \epsilon \exp\left(T\cdot D\left(\frac{k}{T}\bigg\|\frac{1}{2}\right)\right) \;.$$

Equivalently, given that  $\frac{1}{L}\sum_{t=1}^{T}c_{t}=2k-T$ , we also have that

$$\max_{-1 \le \beta \le 1} \prod_{t=1}^{T} (1 + \beta c_t) = \exp\left(T \cdot D\left(\frac{\sum_{t=1}^{T} c_t}{2LT} + \frac{1}{2} \middle\| \frac{1}{2}\right)\right) = \exp\left(T \cdot D\left(\frac{\left|\sum_{t=1}^{T} c_t\right|}{2LT} + \frac{1}{2} \middle\| \frac{1}{2}\right)\right),$$

where in the second equality we used the fact that  $D(x + \frac{1}{2} \| \frac{1}{2}) = D(-x + \frac{1}{2} \| \frac{1}{2})$ . Hence, we have

$$\frac{3}{2}\epsilon \left(\frac{2q}{\sqrt{T}} + 1\right) \exp\left(T \cdot D\left(\frac{1}{2} + \frac{q}{T} \left\| \frac{1}{2}\right)\right) \le \frac{3}{2}\epsilon \left(\frac{2q}{\sqrt{T}} + 1\right) \exp\left(T \cdot D\left(\frac{1}{2} + \frac{\left\|\sum_{t=1}^{T} c_{t}\right\|}{2LT} \left\| \frac{1}{2}\right)\right) \\
= \frac{3}{2}\left(\frac{2q}{\sqrt{T}} + 1\right) \max_{\beta} \epsilon \prod_{t=1}^{T} (1 + c_{t}\beta).$$

Now, let's connect the coin-betting game with OLO, thanks to the next Theorem.

**Theorem 5.5.** Let  $\epsilon_t$  a non-decreasing sequence and A an OLO algorithm that guarantees  $\operatorname{Regret}_t(\mathbf{0}) \leq \epsilon_t$  for any sequence of  $\mathbf{g}_1, \dots, \mathbf{g}_t \in \mathbb{R}^d$  with  $\|\mathbf{g}_i\|_2 \leq L$ . Then, there exists  $\beta_t$  such that  $\mathbf{x}_t = \frac{\beta_t}{L}(\epsilon_T - \sum_{i=1}^{t-1} \langle \mathbf{g}_i, \mathbf{x}_i \rangle)$  and  $\|\beta_t\|_2 \leq 1$  for  $t = 1, \dots, T$ .

*Proof.* Define  $r_t = -\sum_{i=1}^t \langle g_i, x_i \rangle$  the "reward" of the algorithm. So, we have

$$\operatorname{Regret}_t(\boldsymbol{u}) = \sum_{i=1}^t \langle \boldsymbol{g}_i, \boldsymbol{x}_i \rangle - \sum_{i=1}^t \langle \boldsymbol{g}_i, \boldsymbol{u} \rangle = -r_t + \left\langle \sum_{i=1}^t \boldsymbol{g}_i, \boldsymbol{u} \right\rangle \,.$$

Since, we assumed that  $\operatorname{Regret}_t(\mathbf{0}) \leq \epsilon_t$ , we always have  $r_t \geq -\epsilon_t$ . Using this, we claim that  $L\|\mathbf{x}_t\|_2 \leq r_{t-1} + \epsilon_t$  for all  $t=1,\ldots,T$ . To see this, assume that there is a sequence  $\mathbf{g}_1,\ldots,\mathbf{g}_{t-1}$  that gives  $L\|\mathbf{x}_t\|_2 > r_{t-1} + \epsilon_t$ . We then set  $\mathbf{g}_t = L\frac{\mathbf{x}_t}{\|\mathbf{x}_t\|_2}$ . For this sequence, we would have  $r_t = r_{t-1} - L\|\mathbf{x}_t\|_2 < -\epsilon_t$ , that contradicts the observation that  $r_t \geq -\epsilon_t$ .

So, from the fact that  $L\|x_t\|_2 \le r_{t-1} + \epsilon_t \le r_{t-1} + \epsilon_T$  we have that there exists  $\beta_t$  such that  $x_t = \frac{\beta_t}{L}(\epsilon_T + r_{t-1})$  for a  $\beta_t$  and  $\|\beta_t\|_2 \le 1$ .

This theorem informs us of something important: any OLO algorithm that suffers a non-decreasing regret against the null competitor must predict in the form of a "vectorial" coin-betting algorithm.

From this connection to online betting, we now derive a lower bound for online convex optimization.

**Theorem 5.6.** For  $T \in \mathbb{N}$  suppose that there is an online convex optimization algorithm that guarantees regret at most  $\epsilon_T$  against the null competitor on any sequence of T linear and L-Lipschitz losses  $\ell_t : \mathbb{R} \to \mathbb{R}$  for  $t = 1, \ldots, T$ . Let U > 0 be such that  $1 \leq W(\frac{\sqrt{T}UL}{5\epsilon_T}) \leq \frac{\sqrt{T}}{2}$ , then there exists a sequence of  $\mathbf{g}_t$  with  $\|\mathbf{g}_t\|_2 \leq L$  and a competitor  $\mathbf{u} \in \mathbb{R}^d$  with  $\|\mathbf{u}\|_2 = U$ , such that

$$\sum_{t=1}^{T} \langle \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{u} \rangle \geq R_T(U) := UL\sqrt{T} \left( \sqrt{2W \left( \frac{\sqrt{T}UL}{5\epsilon_T} \right)} - 1 \right) - 2UL + \epsilon_T,$$

where  $W: \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$  is the Lambert function.

Moreover, assuming there exists K>0 such that  $\epsilon_T \leq K < \infty$  for all T, we have  $\lim_{T\to +\infty} \frac{R_T(U)}{UL\sqrt{T \ln T}} = 1$ .

*Proof.* Consider the linear losses  $\ell_t(x) = g_t x$ , where  $|g_t| \leq L$ .

Given that the algorithm guarantees a regret of at most  $\epsilon_T$  against the null competitor, from the Theorem 5.5 we have that, if we feed the algorithm with linear losses, we can reinterpret the algorithm as a betting algorithm with initial wealth  $\epsilon_T$  and that guarantees non-negative wealth, where the wealth at time T is defined as  $\epsilon_T - \sum_{t=1}^T g_t x_t$ .

Set 
$$A = W\left(\frac{\sqrt{T}UL}{5\epsilon_T}\right)$$
,  $\tilde{q} = \frac{\sqrt{T}}{2}\sqrt{2A-1}$ , and  $q = \lfloor \tilde{q} \rfloor$ , so that  $\tilde{q} \geq q \geq \tilde{q}-1$ .

Observe that the constraint on U assures that

$$q \le \tilde{q} \le \frac{T^{3/4}}{2} \le \frac{T}{2},\tag{5.1}$$

so we can safely use Theorem 5.3, that tells us that there exists a sequence of  $c_t \in \{-L, L\}^T$  such that  $|\sum_{t=1}^T c_t| \ge 2qL$  and

$$\sum_{t=1}^{T} c_t x_t \le \frac{3}{2} \left( \frac{2q}{\sqrt{T}} + 1 \right) \epsilon_T \exp\left( 2\frac{q^2}{T} \right) \exp\left( 3.1 \frac{q^4}{T^3} \right) - \epsilon_T.$$

Moreover, observe that

$$\exp\left(2\frac{q^2}{T}\right)\exp\left(3.1\frac{q^4}{T^3}\right) \leq \exp\left(2\frac{\tilde{q}^2}{T}\right)\exp\left(3.1\frac{\tilde{q}^4}{T^3}\right) \leq \exp\left(2\frac{\tilde{q}^2}{T}\right)\exp\left(\frac{3.1}{16}\right) \leq \frac{4}{3}\exp\left(2\frac{\tilde{q}^2}{T}\right),$$

where in second inequality we used  $\frac{\tilde{q}^4}{T^3} \leq \frac{1}{16}$  from (5.1).

Set  $g_t = -c_t$  and choose  $u = -U \operatorname{sign}(\sum_{t=1}^T g_t)$ , so we have

$$\sum_{t=1}^{T} g_t(x_t - u) = U \left| \sum_{t=1}^{T} g_t \right| + \sum_{t=1}^{T} g_t x_t$$

$$\geq U \cdot 2qL - 2 \left( \frac{2\tilde{q}}{\sqrt{T}} + 1 \right) \epsilon_T \exp\left( 2\frac{\tilde{q}^2}{T} \right) + \epsilon_T$$

$$\geq UL \cdot (2\tilde{q} - 2) - 2 \left( \frac{2\tilde{q}}{\sqrt{T}} + 1 \right) \epsilon_T \exp\left( 2\frac{\tilde{q}^2}{T} \right) + \epsilon_T.$$

Now, from the condition on U, we have  $\frac{2\tilde{q}}{\sqrt{T}} \geq 1$ , hence we have

$$\sum_{t=1}^{T} g_t(x_t - u) = U \left| \sum_{t=1}^{T} g_t \right| + \sum_{t=1}^{T} g_t x_t$$

$$\geq 4\epsilon_T \left[ \frac{\sqrt{T}UL}{4\epsilon_T} \cdot \frac{2\tilde{q}}{\sqrt{T}} - \frac{2\tilde{q}}{\sqrt{T}} \exp\left(2\frac{\tilde{q}^2}{T}\right) \right] - 2UL + \epsilon_T.$$
(5.2)

Let  $a \geq 1$ , then

$$x^* := \underset{x}{\operatorname{argmax}} \ ax - x \exp(x^2/2) = \sqrt{2W\left(\frac{a\sqrt{e}}{2}\right) - 1}$$
.

So, we have

$$ax^* - x^* \exp((x^*)^2/2) = a\sqrt{2W\left(\frac{a\sqrt{e}}{2}\right) - 1}\left(1 - \frac{1}{2W\left(\frac{a\sqrt{e}}{2}\right)}\right).$$

Hence, our choice of  $\tilde{q}$  maximizes the lower bound in (5.2) and the condition on U assures that  $\frac{\sqrt{T}U}{4\epsilon_T} \geq 1$ . Hence, we obtain

$$\sum_{t=1}^{T} g_t(x_t - u) \ge UL\sqrt{T}\sqrt{2W\left(\frac{\sqrt{T}UL}{4\epsilon_T}\frac{\sqrt{e}}{2}\right) - 1}\left(1 - \frac{1}{2W\left(\frac{\sqrt{T}UL}{4\epsilon_T}\frac{\sqrt{e}}{2}\right)}\right) - 2UL + \epsilon_T.$$

Simplifying the numerical constants and using the elementary inequality  $(1-1/(2x))\sqrt{2x-1} \ge \sqrt{2x}-1$  for  $x \ge 1$  gives the stated bound.

**Remark 5.7.** The leading constant  $\sqrt{2}$  is asymptotically optimal because there exist algorithms with a matching upper bound.

This theorem implies that that OSD with learning rate  $\eta = \frac{\alpha}{L\sqrt{T}}$  does not have the optimal dependency on  $\|u\|_2$  for any  $\alpha > 0$ .

In Chapter 10, we will see that the connection between coin-betting and OLO can also be used to design OLO algorithm. This will give us *optimal unconstrained OLO algorithms with the surprising property of not requiring a learning rate at all.* 

## 5.3 History Bits

The lower bound for OCO is quite standard, the proof presented is a simplified version of the one in Orabona and Pál [2018]. One could also use the function in the lower bound for offline optimization in Nesterov [2004, Section 3.2.1], but it would require the additional assumptions that the d > T and that  $x_t$  lies in the span of the previous subgradients. This limitation on d is unavoidable: without it offline convex optimization becomes easier while Online Convex Optimization is equally hard for any number of dimensions.

On the other hand, both the online learning literature and the optimization one almost ignored the issue of lower bounds for the unconstrained case. The connection between coin-betting and OLO was first unveiled in Orabona and Pál [2016]. Theorem 5.5 is an unpublished result by Ashok Cutkosky, that proved similar and more general results in his PhD thesis [Cutkosky, 2018]. The first lower bound for unconstrained OLO is from Streeter and McMahan [2012], but their proof relied on using the value of  $\inf_T \mathbb{P}\{\sum_{i=1}^T X_i \geq \sqrt{T}\}$  where  $X_i$  are Rademacher random variables. Streeter and McMahan [2012] claim that this value is 7/64 that corresponds to T=6, but they do not provide a proof for it. The same value was also conjectured by Hitczenko and Kwapień [1994] and proved formally only in 2023 by Hollom and Portier [2023]. A proof avoiding completely that step was given by Orabona [2013]. Theorem 5.6 is new: it is a more precise version of the lower bound in Orabona [2013] and it has the asymptotically optimal constant  $\sqrt{2}$ . One way to achieve the optimal constant in lower bounds using the tail of Binomial distributions was shown in Orabona and Pál [2015]. Independently, Zhang et al. [2022] proved a lower bound for unconstrained OCO with the optimal constant but only when  $\epsilon_T = \mathcal{O}(\sqrt{T})$ , with an algorithm with a matching upper bound. The specific method used here to obtain the optimal constant is new. McMahan and Orabona [2014] proposed an algorithm that matches the lower bound up to a multiplicative constant, while Zhang et al. [2022] matched the multiplicative constant too.

More recently, Carmon and Hinder [2024] proved a lower bound of  $\Omega(\|x^* - x_1\|\sqrt{\frac{\ln \frac{\|x^* - x_1\|}{\epsilon}}{T}})$  on the stochastic setting on the expected suboptimality gap. Their lower bound implies the same lower bound we stated on the regret of OCO through the online to batch conversion. However, their lower bound holds for the class of convex Lipschitz functions, while the result here is more general because it holds for linear losses. Their results also implies that the parameter-free algorithm in McMahan and Orabona [2014] coupled with the online-to-batch conversion is minimax optimal for the setting of stochastic unconstrained optimization of Lipschitz convex functions.

## 5.4 Exercises

**Problem 5.1.** Fix U > 0 and  $\mathcal{V} = \mathbb{R}^d$ . Mimicking the proof of Theorem 5.1, prove that for any OCO algorithm there exists a  $\mathbf{u}^*$  and a sequence of loss functions such that  $\operatorname{Regret}_T(\mathbf{u}^*) \geq \frac{1}{2} \|\mathbf{u}^*\|_2 L\sqrt{T}$  where  $\|\mathbf{u}^*\|_2 = U$  and the loss functions are L-Lipschitz w.r.t.  $\|\cdot\|_2$ .

**Problem 5.2.** Extend the proof of Theorem 5.1 to an arbitrary norm  $\|\cdot\|$  to measure the diameter of V and with  $\|g_t\|_{\star} \leq L$ .

## Chapter 6

## **Online Mirror Descent**

In this chapter, we will introduce the Online Mirror Descent (OMD) algorithm. To explain its genesis, I think it is essential to understand what subgradients do. In particular, the negative subgradients are not always pointing towards a direction that minimizes the function.

## **6.1** Subgradients are not Informative

We have seen that in online learning we receive a sequence of loss functions and we have to output a vector before observing the loss function on which we will be evaluated. However, we can gain a lot of intuition if we consider the easy case that the sequence of loss functions is always a fixed function, i.e.,  $\ell_t(x) = \ell(x)$ . If our hypothetical online algorithm does not work in this situation, for sure it won't work on the more general case.

Hence, considering the case of fixed loss functions, let's take a look at the key step in the proof of the upper bound to the regret for Online Subgradient Descent (OSD) in Lemma 2.30. We used the following property of the subgradients:

$$\ell(\boldsymbol{x}_t) - \ell(\boldsymbol{u}) \le \langle \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{u} \rangle. \tag{6.1}$$

In words, to minimize the left hand side of this equation, it is enough to minimize the right hand side, that is nothing else than the instantaneous linear regret on the linear function  $\langle g_t, \cdot \rangle$ . This is the only reason why OSD works! However, I am sure you heard a million of times the (wrong) intuition that gradient points towards the minimum, and you might be tempted to think that the same (even more wrong) intuition holds for subgradients. Indeed, I am sure that even if we proved the regret guarantee based on (6.1), in the back of your mind you keep thinking "yeah, sure, it works because the subgradient tells me where to go to minimize the function". Typically this idea is so strong that I have to present explicit counterexamples to fully convince a person.

So, take a look at the following examples that illustrate the fact that a subgradient does not always point in a direction where the function decreases.

**Example 6.1.** Let  $f(x) = \max[-x_1, x_1 - x_2, x_1 + x_2]$ , see Figure 6.1. The vector  $\mathbf{g} = [1, 1]$  is a subgradient in  $\mathbf{x} = (1, 0)$  of  $f(\mathbf{x})$ . No matter how we choose the stepsize, moving in the direction of the negative subgradient will not decrease the objective function. An even more extreme example is in Figure 6.2, with the function  $f(\mathbf{x}) = \max[x_1^2 + (x_2 + 1)^2, x_1^2 + (x_2 - 1)^2]$ . Here, in the point (1, 0), any positive step in the direction of the negative subgradient will increase the objective function.

In both examples, one might think that it would be enough to add a little bit of noise to move away from the "corners". However, we have to remember that we are in the adversarial setting. So, assuming the adversary see our randomization, it can always present us a function such that our prediction is exactly on a "corner". This means that our analysis of subgradient descent will not have to use the fact that the subgradients point towards descending directions, because it can be false in each single iteration.

**Remark 6.2.** Given the above, one might wonder how much "information" the subgradients carry. It turns out, quite a lot! In fact, for bounded domains in the batch case, i.e., when all the functions are the same, the cutting plane method

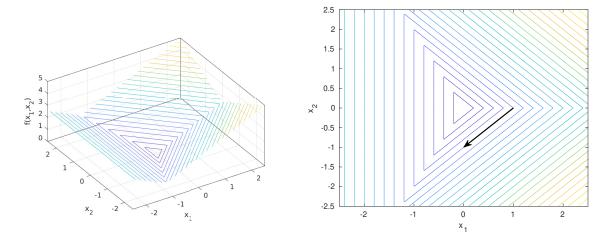

Figure 6.1: 3D plot (left) and level sets (right) of  $f(\mathbf{x}) = \max[-x_1, x_1 - x_2, x_1 + x_2]$ . A negative subgradient is indicated by the black arrow.

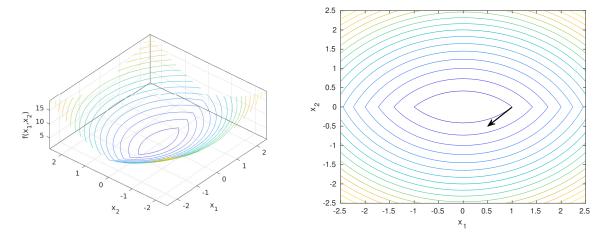

Figure 6.2: 3D plot (left) and level sets (right) of  $f(x) = \max[x_1^2 + (x_2 + 1)^2, x_1^2 + (x_2 - 1)^2]$ . A negative subgradient is indicated by the black arrow.

can optimize the function exponentially fast just using subgradients. However, in the adversarial setting subgradients becomes much weaker than in the batch setting, exactly because the adversary has the power to choose the functions.

## 6.2 Reinterpreting the Online Subgradient Descent Algorithm

How Online Subgradient Descent works? It works exactly as I told you before: thanks to (6.1). But, what does that inequality really mean?

A way to understand how the OSD algorithm works is to think that it minimizes a local approximation of the original objective function. This is not unusual for optimization algorithms, for example the Newton's algorithm constructs an approximation with a Taylor expansion truncated to the second term. Thanks to the definition of subgradients, we can immediately build a linear lower bound to a function f around  $x_0$ :

$$f(x) \geq \tilde{f}(x) := f(x_0) + \langle g, x - x_0 \rangle, \ \forall x \in \mathcal{V}$$
.

So, in our setting, this would mean that we update the online algorithm with the minimizer of a linear approximation

of the loss function you received. Unfortunately, minimizing a linear function is unlikely to give us a good online algorithm. Indeed, over unbounded domains the minimum of a linear function is  $-\infty$ .

So, let's introduce the other key concept: we constraint the minimization of this lower bound only in a neighborhood of  $x_0$ , where we have good reason to believe that the approximation is more precise. Moreover, in online learning it makes sense not to go too far from the previous iteration because the losses are different in each step and we do now want to give too much importance to the current loss. Coding the neighborhood constraint with a  $L_2$  squared distance from  $x_0$  less than some positive number h, we might think to use the following update

$$egin{aligned} m{x}_{t+1} &= rgmin_{m{x} \in \mathcal{V}} f(m{x}_t) + \langle m{g}, m{x} - m{x}_t 
angle \ & ext{s.t.} \ \|m{x}_t - m{x}\|^2 \leq h \ . \end{aligned}$$

Equivalently, for some  $\eta > 0$ , we can consider the unconstrained formulation

$$\underset{\boldsymbol{x} \in \mathcal{V}}{\operatorname{argmin}} \ \hat{f}(\boldsymbol{x}) := f(\boldsymbol{x}_0) + \langle \boldsymbol{g}, \boldsymbol{x} - \boldsymbol{x}_0 \rangle + \frac{1}{2\eta} \|\boldsymbol{x}_0 - \boldsymbol{x}\|_2^2.$$
 (6.2)

This is a well-defined update scheme, that hopefully moves  $x_t$  closer to the optimum of f. See Figure 6.3 for a graphical representation in one-dimension.

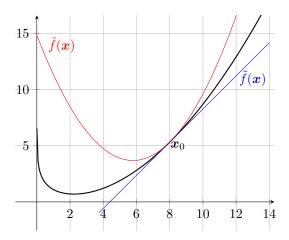

Figure 6.3: Approximations of f(x).

And now the final element of our story: the argmin in (6.2) is exactly the update we used in OSD! Indeed, solving the argmin and completing the square, we get

$$\underset{\boldsymbol{x} \in \mathcal{V}}{\operatorname{argmin}} \langle \boldsymbol{g}_{t}, \boldsymbol{x} \rangle + \frac{1}{2\eta_{t}} \|\boldsymbol{x}_{t} - \boldsymbol{x}\|_{2}^{2} = \underset{\boldsymbol{x} \in \mathcal{V}}{\operatorname{argmin}} \|\eta_{t} \boldsymbol{g}_{t}\|^{2} + 2\eta_{t} \langle \boldsymbol{g}_{t}, \boldsymbol{x} - \boldsymbol{x}_{t} \rangle + \|\boldsymbol{x}_{t} - \boldsymbol{x}\|_{2}^{2}$$

$$= \underset{\boldsymbol{x} \in \mathcal{V}}{\operatorname{argmin}} \|\boldsymbol{x} - \boldsymbol{x}_{t} + \eta_{t} \boldsymbol{g}_{t}\|_{2}^{2}$$

$$= \Pi_{\mathcal{V}}(\boldsymbol{x}_{t} - \eta_{t} \boldsymbol{g}_{t}).$$
(6.3)

where  $\Pi_{\mathcal{V}}$  is the Euclidean projection onto  $\mathcal{V}$ , i.e.,  $\Pi_{\mathcal{V}}(x) = \operatorname{argmin}_{x \in \mathcal{V}} \|x - y\|_2$ .

The new way to write the update of OSD in (6.2) will be the core ingredient for designing Online Mirror Descent. In fact, OMD is a strict generalization of that update when we use a different way to measure the locality of x from  $x_t$ . That is, we measured the distance between to the current point with the squared  $L_2$  norm. What happens if we change the norm? Do we even have to use a norm?

To answer these questions we have to introduce another useful mathematical object: the Bregman divergence.

## 6.3 Convex Analysis Bits: Bregman Divergence

We first give a new definition, a slightly stronger notion of convexity.

**Definition 6.3** (Strictly Convex Function). Let  $f: \mathcal{V} \subseteq \mathbb{R}^d \to \mathbb{R}$  and  $\mathcal{V}$  a convex set. f is strictly convex if

$$f(\alpha x + (1 - \alpha)y) < \alpha f(x) + (1 - \alpha)f(y), \forall x, y \in \mathcal{V}, x \neq y, 0 < \alpha < 1.$$

From the definition, it is immediate to see that strong convexity w.r.t. any norm implies strict convexity. Note that for a differentiable function, strict convexity also implies that  $f(y) > f(x) + \langle \nabla f(x), y - x \rangle$  for  $x \neq y$  [Bauschke and Combettes, 2011, Proposition 17.13].

We now define our new notion of "distance".

**Definition 6.4** (Bregman Divergence). Let  $\psi : \mathcal{X} \to \mathbb{R}$  be strictly convex and differentiable on  $\operatorname{int} \mathcal{X} \neq \{\}$ . The **Bregman Divergence** w.r.t.  $\psi$  is denoted by  $B_{\psi} : \mathcal{X} \times \operatorname{int} \mathcal{X} \to \mathbb{R}$  defined as

$$B_{\psi}(\boldsymbol{x};\boldsymbol{y}) = \psi(\boldsymbol{x}) - \psi(\boldsymbol{y}) - \langle \nabla \psi(\boldsymbol{y}), \boldsymbol{x} - \boldsymbol{y} \rangle$$
.

From the definition, we see that the Bregman divergence is always non-negative for  $x, y \in \operatorname{int} \mathcal{X}$ , from the convexity of  $\psi$ . However, something stronger holds. By the strict convexity of  $\psi$ , for fixed a point  $y \in \operatorname{int} \mathcal{X}$  we have that  $\psi(x) \geq \psi(y) + \langle \nabla \psi(y), x - y \rangle$ ,  $\forall y \in \mathcal{X}$ , with equality only for y = x. Hence, the strict convexity allows us to use the Bregman divergence as a similarity measure between x and y. Moreover, this similarity measure *changes* with the reference point y. This also implies that, as you can see from the definition, the Bregman divergence is not symmetric.

Let me give you some more intuition on the concept of the Bregman divergence. Consider the case that  $\psi$  is twice differentiable in an open ball B around y and  $x \in B$ . So, by the Taylor's theorem, there exists  $0 \le \alpha \le 1$  such that

$$B_{\psi}(\boldsymbol{x};\boldsymbol{y}) = \psi(\boldsymbol{x}) - \psi(\boldsymbol{y}) - \nabla \psi(\boldsymbol{y})^{\top}(\boldsymbol{x} - \boldsymbol{y}) = \frac{1}{2}(\boldsymbol{x} - \boldsymbol{y})^{\top} \nabla^{2} \psi(\boldsymbol{z})(\boldsymbol{x} - \boldsymbol{y}),$$

where  $z = \alpha x + (1 - \alpha)y$ . Hence, we are using a *squared local norm* that depends on the Hessian of  $\psi$ . Different areas of the space will have a different value of the Hessian, and so the Bregman will behave differently. We will use this exact idea in the local norm analysis of Online Mirror Descent (Section 6.5) and Follow-the-Regularized-Leader (Section 7.4).

We can also lower bound the Bregman divergence if the function  $\psi$  is strongly convex. In particular, if  $\psi$  is  $\lambda$ -strongly convex w.r.t. a norm  $\|\cdot\|$  in int  $\mathcal{X}$ , then we have

$$B_{\psi}(\boldsymbol{x};\boldsymbol{y}) \ge \frac{\lambda}{2} \|\boldsymbol{x} - \boldsymbol{y}\|^2. \tag{6.4}$$

Example 6.5. If  $\psi(x) = \frac{1}{2} \|x\|_2^2$ , then  $B_{\psi}(x; y) = \frac{1}{2} \|x\|_2^2 - \frac{1}{2} \|y\|_2^2 - \langle y, x - y \rangle = \frac{1}{2} \|x - y\|_2^2$ .

**Example 6.6.** Let  $\mathcal{V} = \{ \boldsymbol{x} \in \mathbb{R}^d : x_i \geq 0, \|\boldsymbol{x}\|_1 = 1 \}$ ,  $\mathcal{X} = \mathbb{R}^d_{\geq 0}$ , and  $\psi(\boldsymbol{x}) = \sum_{i=1}^d x_i \ln x_i$ , the negative entropy. Then, for all  $\boldsymbol{x} \in \mathcal{X}$  and  $\boldsymbol{y} \in \operatorname{int} \mathcal{X}$  we have

$$B_{\psi}(\boldsymbol{x};\boldsymbol{y}) = \sum_{i=1}^{d} (x_i \ln x_i - y_i \ln y_i - (\ln(y_i) + 1)(x_i - y_i)) = \sum_{i=1}^{d} \left( x_i \ln \frac{x_i}{y_i} - x_i + y_i \right) .$$

This is called the generalized Kullback-Leibler divergence, where "generalized" is due to the fact that x and y do not have to be discrete probability distributions.

We also have the following immediate lemma that links the Bregman divergences between 3 points.

**Lemma 6.7** ([Chen and Teboulle, 1993]). Let  $B_{\psi}$  the Bregman divergence w.r.t.  $\psi : \mathcal{X} \to \mathbb{R}$ . Then, for any three points  $x, y \in \text{int } \mathcal{X}$  and  $z \in \mathcal{X}$ , the following identity holds

$$B_{\psi}(\boldsymbol{z}; \boldsymbol{x}) + B_{\psi}(\boldsymbol{x}; \boldsymbol{y}) - B_{\psi}(\boldsymbol{z}; \boldsymbol{y}) = \langle \nabla \psi(\boldsymbol{y}) - \nabla \psi(\boldsymbol{x}), \boldsymbol{z} - \boldsymbol{x} \rangle$$
.

## **6.4** Online Mirror Descent

Based on what we said before, we can start from the equivalent formulation of the OSD update

$$\boldsymbol{x}_{t+1} = \operatorname*{argmin}_{\boldsymbol{x} \in \mathcal{V}} \langle \boldsymbol{g}_t, \boldsymbol{x} \rangle + \frac{1}{2\eta_t} \|\boldsymbol{x}_t - \boldsymbol{x}\|_2^2,$$

and we can change the last term with another measure of distance. In particular, using the Bregman divergence w.r.t. a function  $\psi$ , we have

$$\boldsymbol{x}_{t+1} = \operatorname*{argmin}_{\boldsymbol{x} \in \mathcal{V}} \langle \boldsymbol{g}_t, \boldsymbol{x} \rangle + \frac{1}{\eta_t} B_{\psi}(\boldsymbol{x}; \boldsymbol{x}_t),$$

where we assumed that the argmin exists. These two updates are exactly the same when  $\psi(x) = \frac{1}{2} ||x||_2^2$ . So, we get the Online Mirror Descent algorithm in Algorithm 6.1.

#### Algorithm 6.1 Online Mirror Descent

**Require:** Non-empty closed convex  $\mathcal{V} \subset \mathcal{X} \subseteq \mathbb{R}^d$ ,  $\psi : \mathcal{X} \to \mathbb{R}$  strictly convex and differentiable on int  $\mathcal{X}$ ,  $x_1 \in \operatorname{int} \mathcal{X} \cap \mathcal{V}$ ,  $\eta_1, \ldots, \eta_T > 0$ 

- 1: for t = 1 to T do
- 2: Output  $x_t \in \mathcal{V}$
- 3: Pay  $\ell_t(\boldsymbol{x}_t)$  for  $\ell_t: \mathcal{V} \to \mathbb{R}$  subdifferentiable in  $\mathcal{V}$
- 4: Set  $\boldsymbol{g}_t \in \partial \ell_t(\boldsymbol{x}_t)$
- 5: Set  $x_{t+1} \in \operatorname{argmin}_{x \in \mathcal{V}} \langle g_t, x \rangle + \frac{1}{n_t} B_{\psi}(x; x_t)$
- 6: end for

However, without an additional assumption, this algorithm has a problem. Can you see it? The problem is that  $x_{t+1}$  might be on the boundary of  $\mathcal{V}$  and in the next step we would have to evaluate  $B_{\psi}(x; x_{t+1})$  for a point on the boundary of  $\mathcal{V}$ . Given that  $\mathcal{V} \subset \mathcal{X}$ , we might end up on the boundary of X where the Bregman is not defined!

To fix this problem, different sufficient conditions can be used. In the following, we will use either one of the following assumptions:

$$\lim_{\lambda \to 0} \langle \nabla \psi(\boldsymbol{x} + \lambda(\boldsymbol{y} - \boldsymbol{x})), \boldsymbol{y} - \boldsymbol{x} \rangle = -\infty, \quad \forall \boldsymbol{x} \in \text{bdry } \mathcal{X}, \forall \boldsymbol{y} \in \text{int } \mathcal{X}$$
(6.5)

$$\mathcal{V} \subseteq \operatorname{int} \mathcal{X}$$
. (6.6)

If either of these conditions is true and the argmin exists on each round then the algorithm is well-defined as proved in the following theorem.

**Theorem 6.8.** Let  $B_{\psi}$  the Bregman divergence w.r.t.  $\psi : \mathcal{X} \to \mathbb{R}$ . Let  $\mathcal{V} \subseteq \mathcal{X}$  a non-empty closed convex set. Assume (6.5) or (6.6) hold and, with the notation in Algorithm 6.1, the argmin exists on all rounds. Then,  $x_{t+1} \in \operatorname{int} \mathcal{X}$ .

*Proof.* In the case that (6.6) holds, we have that  $x_{t+1} \in \mathcal{V}$  implies immediately that  $x_{t+1} \in \text{int } \mathcal{X}$ .

Let's now assume that (6.5) holds and let's prove it by induction. The base case is true by the definition of  $x_1$ . Let's now assume that  $x_t \in \operatorname{int} \mathcal{X}$  and let's prove that  $x_{t+1} \in \operatorname{int} \mathcal{X}$ . We will prove it by contradiction. So, assume that  $x_{t+1} \in \operatorname{bdry} \mathcal{X}$ . Set  $z \in \operatorname{int} \mathcal{X} \cap \mathcal{V}$  and define  $\phi(\lambda) = \langle \eta_t g_t, (1-\lambda)x_{t+1} + \lambda z \rangle + B_{\psi}((1-\lambda)x_{t+1} + \lambda z; x_t)$  for  $\lambda \in (0,1)$ . From (6.5), we have that

$$\lim_{\lambda \to 0} \phi'(\lambda) = \lim_{\lambda \to 0} \langle \eta_t \boldsymbol{g}_t, \boldsymbol{z} - \boldsymbol{x}_{t+1} \rangle + \langle \nabla \psi(\boldsymbol{x}_{t+1} + \lambda(\boldsymbol{z} - \boldsymbol{x}_{t+1})) - \nabla \psi(\boldsymbol{x}_t), \boldsymbol{z} - \boldsymbol{x}_{t+1} \rangle = -\infty.$$

Hence, there exists  $\epsilon > 0$  such that

$$\langle \eta_t \boldsymbol{g}_t, \boldsymbol{x}_{\epsilon} \rangle + B_{\psi}(\boldsymbol{x}_{\epsilon}; \boldsymbol{x}_t) = \phi(\epsilon) < \phi(0) = \langle \eta_t \boldsymbol{g}_t, \boldsymbol{x}_{t+1} \rangle + B_{\psi}(\boldsymbol{x}_{t+1}; \boldsymbol{x}_t),$$

where  $x_{\epsilon} := (1 - \epsilon)x_{t+1} + \epsilon z \in \operatorname{int} \mathcal{X} \cap \mathcal{V}$ . However, this contradicts, the definition of  $x_{t+1}$  as an argmin, proving that  $x_{t+1}$  must be in  $\operatorname{int} \mathcal{X}$ .

When (6.5) holds, this theorem implies that the predictions of the algorithm always stay in the interior of the feasible set without the need for any projection. If in addition V = X, the update of the algorithm is the solution of an unconstrained problem because the feasible set is implicit in the Bregman divergence.

Now we have a well-defined algorithm, but does it guarantee a sublinear regret? We know that at least in one case it recovers the OSD algorithm, that does work. So, from an intuitive point of view, how well the algorithm work should depend on some characteristic on  $\psi$ . In particular, a key property will be the *strong convexity* of  $\psi$ . The strong convexity also takes care of the existence of the argmin in the algorithm, thanks to next Theorem.

**Theorem 6.9.** Let  $\lambda > 0$  and  $f : \mathbb{R}^d \to (-\infty, +\infty]$  proper, closed, and  $\lambda$ -strongly convex w.r.t.  $\| \cdot \|$  on its domain. Assume dom  $\partial f \neq \{\}$ . Then, f has exactly one minimizer.

*Proof.* Let  $y \in \text{dom } \partial f$  and  $g \in \partial f(y)$ . From Lemma 4.2, for any  $x \in \mathbb{R}^d$ , we have

$$egin{split} f(oldsymbol{x}) &\geq f(oldsymbol{y}) + \langle oldsymbol{g}, oldsymbol{x} - oldsymbol{y} 
angle + rac{\lambda}{2} \|oldsymbol{x} - oldsymbol{y}\|^2 \ &\geq f(oldsymbol{y}) - \|oldsymbol{g}\|_\star \|oldsymbol{x}\| - \langle oldsymbol{g}, oldsymbol{y} 
angle + rac{\lambda}{2} (\|oldsymbol{x}\| - \|oldsymbol{y}\|)^2 \ &= f(oldsymbol{y}) - \|oldsymbol{g}\|_\star \|oldsymbol{x}\| - \langle oldsymbol{g}, oldsymbol{y} 
angle + rac{\lambda}{2} (\|oldsymbol{x}\|^2 + \|oldsymbol{y}\|^2 - 2\|oldsymbol{x}\| \|oldsymbol{y}\|), \end{split}$$

where in the second inequality we used the reverse triangle inequality and the definition of dual norms. From the above, we have that  $\lim_{\|\boldsymbol{x}\|\to\infty} f(\boldsymbol{x}) = +\infty$ . In turn, this implies that the level sets of f are bounded. From the assumption that f is closed, we get that the level sets are compact. Hence, for any  $\boldsymbol{y}$  in  $\mathrm{dom}\, f$ , the minimum of f is the same of the minimum of f over the set  $\{\boldsymbol{x}: f(\boldsymbol{x}) \leq f(\boldsymbol{y})\}$ , that is the minimum over a compact set, that exists by the Weierstrass theorem, Theorem E.8. The uniqueness is given by the fact that strongly convex function are strictly convex.

To analyze OMD, we first prove a one step relationship, similar to the one we proved for Online Gradient Descent and OSD. Note how in this Lemma, we will use a lot of the concepts we introduced till now: strong convexity, dual norms, subgradients, etc. In a way, over the past sections I slowly prepared you to be able to prove this lemma.

**Lemma 6.10.** Let  $B_{\psi}$  the Bregman divergence w.r.t.  $\psi : \mathcal{X} \to \mathbb{R}$  and assume  $\psi$  to be proper, closed, and  $\lambda$ -strongly convex with respect to  $\|\cdot\|$  in  $V \cap \operatorname{int} \mathcal{X}$ . Let  $V \subseteq \mathcal{X}$  a non-empty closed convex set. Assume (6.5) or (6.6) hold. Then, with the notation in Algorithm 6.1, for all t we have that  $x_{t+1}$  exists, it is unique, and it is in the interior of  $\mathcal{X}$ . Moreover,  $\forall u \in \mathcal{V}$ , the following inequality holds

$$\eta_t(\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) \leq \eta_t \langle \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{u} \rangle \leq B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_t) - B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_{t+1}) - B_{\psi}(\boldsymbol{x}_{t+1}; \boldsymbol{x}_t) + \langle \eta_t \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{x}_{t+1} \rangle \\
\leq B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_t) - B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_{t+1}) + \frac{\eta_t^2}{2\lambda} \|\boldsymbol{g}_t\|_{\star}^2.$$

*Proof.* First of all, in each round  $x_{t+1}$  exists using Theorem 6.9 and the fact that  $B_{\psi}(\cdot; x_t)$  is proper, closed, and strongly convex. Moreover, from Theorem 6.8,  $x_t \in \text{int } \mathcal{X}$  for all t.

Now, from the optimality condition in Theorem 2.8 for the update of OMD, we have

$$\langle \eta_t \boldsymbol{q}_t + \nabla \psi(\boldsymbol{x}_{t+1}) - \nabla \psi(\boldsymbol{x}_t), \boldsymbol{u} - \boldsymbol{x}_{t+1} \rangle \ge 0, \ \forall \boldsymbol{u} \in \mathcal{V}.$$
 (6.7)

Hence, we have that

$$\langle \eta_{t} \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{u} \rangle 
= \langle \nabla \psi(\boldsymbol{x}_{t}) - \nabla \psi(\boldsymbol{x}_{t+1}) - \eta_{t} \boldsymbol{g}_{t}, \boldsymbol{u} - \boldsymbol{x}_{t+1} \rangle + \langle \nabla \psi(\boldsymbol{x}_{t+1}) - \nabla \psi(\boldsymbol{x}_{t}), \boldsymbol{u} - \boldsymbol{x}_{t+1} \rangle + \langle \eta_{t} \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{x}_{t+1} \rangle 
\leq \langle \nabla \psi(\boldsymbol{x}_{t+1}) - \nabla \psi(\boldsymbol{x}_{t}), \boldsymbol{u} - \boldsymbol{x}_{t+1} \rangle + \langle \eta_{t} \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{x}_{t+1} \rangle 
= B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_{t}) - B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_{t+1}) - B_{\psi}(\boldsymbol{x}_{t+1}; \boldsymbol{x}_{t}) + \langle \eta_{t} \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{x}_{t+1} \rangle 
\leq B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_{t}) - B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_{t+1}) - \frac{\lambda}{2} \|\boldsymbol{x}_{t} - \boldsymbol{x}_{t+1}\|^{2} + \eta_{t} \|\boldsymbol{g}_{t}\|_{\star} \|\boldsymbol{x}_{t} - \boldsymbol{x}_{t+1}\| 
\leq B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_{t}) - B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_{t+1}) + \frac{\eta_{t}^{2}}{2\lambda} \|\boldsymbol{g}_{t}\|_{\star}^{2},$$

where in the second inequality we used (6.7), in the second equality we used Lemma 6.7, in the second inequality we used the definition of dual norm and (6.4) because  $\psi$  is  $\lambda$ -strong convex w.r.t.  $\|\cdot\|$ , finally in the last inequality we used the fact that  $ax - \frac{b}{2}x^2 \le \frac{a^2}{2b}$  for  $x \in \mathbb{R}$  and a, b > 0. The lower bound with the function values is due, as usual, to the definition of subgradients.

We now see how to use this one step relationship to prove a regret bound, that will finally show us if and when this entire construction is a good idea. In fact, it is worth stressing that the above motivation is not enough in any way to justify the existence of the OMD algorithm. Also, in the next section we will explain why the algorithm is called Online "Mirror" Descent.

We can now prove a regret bound for OMD.

**Theorem 6.11.** Set  $x_1 \in \mathcal{V}$  such that  $\psi$  is differentiable in  $x_1$ . Assume  $\eta_{t+1} \leq \eta_t$ ,  $t = 1, \ldots, T$ . Then, under the assumptions of Lemma 6.10 and  $\forall u \in \mathcal{V}$ , the following regret bounds hold

$$\sum_{t=1}^T (\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) \leq \max_{1 \leq t \leq T} \frac{B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_t)}{\eta_T} + \frac{1}{2\lambda} \sum_{t=1}^T \eta_t \|\boldsymbol{g}_t\|_{\star}^2.$$

Moreover, if  $\eta_t$  is constant, i.e.,  $\eta_t = \eta \ \forall t = 1, \cdots, T$ , we have

$$\sum_{t=1}^T (\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) \leq \frac{B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_1)}{\eta} + \frac{\eta}{2\lambda} \sum_{t=1}^T \|\boldsymbol{g}_t\|_{\star}^2.$$

*Proof.* Fix  $u \in \mathcal{V}$ . As in the proof of OGD, dividing the inequality in Lemma 6.10 by  $\eta_t$  and summing from t = $1, \cdots, T$ , we get

$$\begin{split} \sum_{t=1}^{T} (\ell_{t}(\boldsymbol{x}_{t}) - \ell_{t}(\boldsymbol{u})) &\leq \sum_{t=1}^{T} \left( \frac{1}{\eta_{t}} B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_{t}) - \frac{1}{\eta_{t}} B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_{t+1}) \right) + \sum_{t=1}^{T} \frac{\eta_{t}}{2\lambda} \|\boldsymbol{g}_{t}\|_{\star}^{2} \\ &= \frac{1}{\eta_{1}} B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_{1}) - \frac{1}{\eta_{T}} B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_{T+1}) + \sum_{t=1}^{T-1} \left( \frac{1}{\eta_{t+1}} - \frac{1}{\eta_{t}} \right) B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_{t+1}) + \sum_{t=1}^{T} \frac{\eta_{t}}{2\lambda} \|\boldsymbol{g}_{t}\|_{\star}^{2} \\ &\leq \frac{1}{\eta_{1}} D^{2} + D^{2} \sum_{t=1}^{T-1} \left( \frac{1}{\eta_{t+1}} - \frac{1}{\eta_{t}} \right) + \sum_{t=1}^{T} \frac{\eta_{t}}{2\lambda} \|\boldsymbol{g}_{t}\|_{\star}^{2} \\ &= \frac{1}{\eta_{1}} D^{2} + D^{2} \left( \frac{1}{\eta_{T}} - \frac{1}{\eta_{1}} \right) + \sum_{t=1}^{T} \frac{\eta_{t}}{2\lambda} \|\boldsymbol{g}_{t}\|_{\star}^{2} \\ &= \frac{D^{2}}{\eta_{T}} + \sum_{t=1}^{T} \frac{\eta_{t}}{2\lambda} \|\boldsymbol{g}_{t}\|_{\star}^{2}, \end{split}$$

where we denoted by  $D^2 = \max_{1 \le t \le T} B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_t)$ .

The second statement is left as an exercise.

In words, OMD allows us to prove regret guarantees that depend on arbitrary couple of dual norms  $\|\cdot\|$  and  $\|\cdot\|_{\star}$ . In particular, the primal norm will be used to measure the feasible set  $\mathcal{V}$  or the distance between the competitor and the initial point, and the dual norm will be used to measure the gradients. If you happen to know something about these quantities, we can choose the most appropriate couple of norm to guarantee a small regret. The only thing you need is a function  $\psi$  that is strongly convex with respect to the primal norm you have chosen.

Overall, the regret bound is still of the order of  $\sqrt{T}$  for Lipschitz functions, that only difference is that now the Lipschitz constant is measured with a different norm. Also, everything we did for Online Subgradient Descent can be trivially used here. For example, we can slightly generalize the stepsizes we saw in Section 4.2 to

$$\eta_t = \frac{D\sqrt{2\lambda}}{2\sqrt{\sum_{i=1}^t \|\boldsymbol{g}_i\|_{\star}^2}}$$

to achieve a regret upper bound of  $\frac{D}{\sqrt{\lambda}}\sqrt{2\sum_{t=1}^{T}\|\boldsymbol{g}_{t}\|_{\star}^{2}}$ .

In Sections 6.6 and 6.7, we will see practical examples of OMD that guarantee strictly better regret than OSD. As we did in the case of AdaGrad, the better guarantee will depend on the shape of the domain and the characteristics of the subgradients.

Next, we see the meaning of the "Mirror", but first we need another mathematical tool: Fenchel conjugates.

#### 6.4.1 Convex Analysis Bits: Fenchel Conjugate

**Definition 6.12** (Closed Function). A function  $f: \mathcal{V} \subseteq \mathbb{R}^d \to [-\infty, +\infty]$  is **closed** iff  $\{x: f(x) \leq \alpha\}$  is closed for every  $\alpha \in \mathbb{R}$ .

Note that in a Hausdorff space a function is closed iff it is lower semicontinuous [Bauschke and Combettes, 2011, Lemma 1.24].

**Example 6.13.** The indicator function of a set  $V \subset \mathbb{R}^d$ , is closed iff V is closed.

**Definition 6.14** (Fenchel Conjugate). For a function  $f : \mathbb{R}^d \to [-\infty, \infty]$ , we define the **Fenchel conjugate**  $f^* : \mathbb{R}^d \to [-\infty, \infty]$  as

$$f^{\star}(\boldsymbol{\theta}) = \sup_{\boldsymbol{x} \in \mathbb{R}^d} \langle \boldsymbol{\theta}, \boldsymbol{x} \rangle - f(\boldsymbol{x}) .$$

From the definition we immediately obtain the Fenchel-Young's inequality for proper functions:

$$\langle \boldsymbol{\theta}, \boldsymbol{x} \rangle < f(\boldsymbol{x}) + f^{\star}(\boldsymbol{\theta}), \ \forall \boldsymbol{x}, \boldsymbol{\theta} \in \mathbb{R}^d.$$

Moreover,  $f^*$  is always convex and closed, regardless of the convexity of f [Bauschke and Combettes, 2011, Proposition 13.11].

We have the following useful properties for the Fenchel conjugate.

**Theorem 6.15** ([Rockafellar, 1970, Theorem 12.2]). Let f a convex function. Then,  $f^*$  is a closed convex function, proper iff f is proper. Moreover, if f is also closed then  $f^{**} = f$ .

**Theorem 6.16.** Let  $f: \mathbb{R}^d \to (-\infty, +\infty]$  be proper. Then, the following conditions are equivalent:

- (a)  $\theta \in \partial f(x)$ .
- (b)  $\langle \boldsymbol{\theta}, \boldsymbol{y} \rangle f(\boldsymbol{y})$  achieves its supremum in  $\boldsymbol{y}$  at  $\boldsymbol{y} = \boldsymbol{x}$ .
- (c)  $f(x) + f^*(\theta) = \langle \theta, x \rangle$ .

Moreover, if f is also convex and closed, we have an additional equivalent condition

(d)  $\mathbf{x} \in \partial f^{\star}(\boldsymbol{\theta})$ .

*Proof.* Let's prove (a)⇔(b). From the definition of subgradient, we have

$$f(\boldsymbol{y}) \geq f(\boldsymbol{x}) + \langle \boldsymbol{\theta}, \boldsymbol{y} - \boldsymbol{x} \rangle, \forall \boldsymbol{y}$$

that is

$$\langle \boldsymbol{\theta}, \boldsymbol{x} \rangle - f(\boldsymbol{x}) > \langle \boldsymbol{\theta}, \boldsymbol{y} \rangle - f(\boldsymbol{y}), \forall \boldsymbol{y}.$$

Then, (b) $\Leftrightarrow$ (c) by definition of  $f^*(\theta)$ .

If f is also convex and closed, then  $f^{\star\star}=f$  is proper by Theorem 6.15. Hence, (c) is equivalent to  $f^{\star\star}(x)+f^{\star}(\theta)=\langle \theta,x\rangle$ , that is equivalent to (d) by following the same reasoning as above.

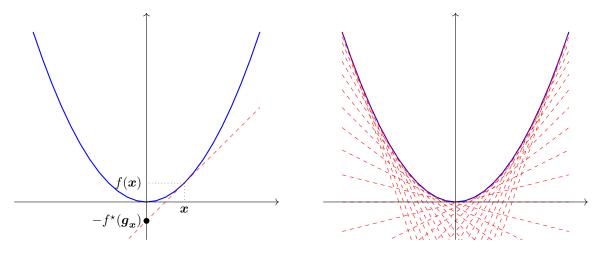

Figure 6.4: A geometric interpretation of the Fenchel conjugate.

The above theorem implies that for convex, closed, and proper functions  $\partial f^*$  is the inverse of  $\partial f$ , i.e.,  $\mathbf{g} \in \partial f(\mathbf{x})$  iff  $\mathbf{x} \in \partial f^*(\mathbf{g})$ .

In the following, we will not need a geometric intuition of the concept of Fenchel conjugates in order to use them. However, for some people geometric intuitions help remember better, so let's briefly discuss it. Let f be convex, closed, and proper. Let  $x \in \text{dom } \partial f$  and use a subgradient  $g_x \in \partial f(x)$  to construct a linear lower bound around x passing through f(x) as  $\tilde{f}_x(y) := f(x) + \langle g_x, y - x \rangle$ . Moreover, from the point (c) of the previous theorem, we have

$$\tilde{f}_{x}(\mathbf{0}) = f(x) - \langle g_{x}, x \rangle = -f^{\star}(g_{x}).$$

Hence, we have  $-f^{\star}(g_x)$  is the value of  $\tilde{f}_x$  at x=0, see Figure 6.4 (left). This is mildly interesting, but not very illuminating, so let's dig deeper. This fact allows us to show that we can recover f as the point-wise maximum of all its tangents, see Figure 6.4 (right). In fact, from the above equality, we also have that  $\tilde{f}_x(y) = -f^{\star}(g_x) + \langle g_x, y \rangle$ . Hence, for any y we obtain

$$\sup_{\boldsymbol{x} \in \text{dom } \partial f} \tilde{f}_{\boldsymbol{x}}(\boldsymbol{y}) = \sup_{\boldsymbol{x} \in \text{dom } \partial f} -f^{\star}(\boldsymbol{g}_{\boldsymbol{x}}) + \langle \boldsymbol{g}_{\boldsymbol{x}}, \boldsymbol{y} \rangle \leq \sup_{\boldsymbol{g}} -f^{\star}(\boldsymbol{g}) + \langle \boldsymbol{g}, \boldsymbol{y} \rangle = f^{\star\star}(\boldsymbol{y}) = f(\boldsymbol{y}),$$

where in last equality we used Theorem 6.15. Moreover, for  $y \in \text{dom } \partial f$ , we also have

$$\sup_{\boldsymbol{x} \in \text{dom } \partial f} \tilde{f}_{\boldsymbol{x}}(\boldsymbol{y}) = \sup_{\boldsymbol{x} \in \text{dom } \partial f} f(\boldsymbol{x}) + \langle \boldsymbol{g}_{\boldsymbol{x}}, \boldsymbol{y} - \boldsymbol{x} \rangle \geq f(\boldsymbol{y}) \ .$$

So, overall we have  $\sup_{\boldsymbol{x}\in\operatorname{dom}\partial f}\tilde{f}_{\boldsymbol{x}}(\boldsymbol{y})=f(\boldsymbol{y})$  for any  $\boldsymbol{y}\in\operatorname{dom}\partial f$ . Hence, the Fenchel conjugate allows us to reason about functions using their tangent hyperplanes, whose information is in the Fenchel conjugate, without losing anything.

Another way to quantify the above is the fact that the domain of  $f^*$  contains all the possible subgradients of f.

**Corollary 6.17.** Let  $f: \mathbb{R}^d \to (-\infty, +\infty]$  proper. Then,  $\{g \in \partial f(x) : x \in \mathbb{R}^d\} \subseteq \text{dom } f^*$ .

*Proof.* From Theorem 6.16 (a) and (b), we have

$$g \in \partial f(x) \Leftrightarrow f(x) + f^{\star}(g) = \langle g, x \rangle \Rightarrow f^{\star}(g) < +\infty$$
.

Note that there are cases where the domain of  $f^*$  contains vectors that are not subgradients. For example,  $f(x) = \exp(-x)$  and  $f^*(0) = \sup_x - \exp(-x) = 0 < \infty$  and 0 is not a derivative of f.

**Example 6.18.** Let  $f(x) = \exp(x)$ , hence we have  $f^*(\theta) = \max_x x\theta - \exp(x)$ . Solving the optimization, we have

that 
$$x^* = \ln(\theta)$$
 if  $\theta > 0$ . Hence,  $f^*(\theta) = \begin{cases} \theta \ln \theta - \theta, & \text{if } \theta > 0 \\ 0, & \text{if } \theta = 0. \\ +\infty, & \text{if } \theta < 0 \end{cases}$ 

**Example 6.19** (Conjugate of inner product). Let  $f(x) = \langle x, x \rangle$  where  $x \neq 0 \in \mathbb{R}^d$ . Then

$$f^{\star}(\boldsymbol{\theta}) = \sup_{\boldsymbol{x} \in \mathbb{R}^d} \langle \boldsymbol{\theta} - \boldsymbol{z}, \boldsymbol{x} \rangle = \begin{cases} 0, & \boldsymbol{\theta} = \boldsymbol{z} \\ +\infty, & otherwise. \end{cases}$$

**Example 6.20** (Conjugate of hinge loss). Let  $f(x) = \max(1 - \langle z, x \rangle, 0)$  where  $z \in \mathbb{R}^d$  and let's calculate  $f^*(\theta)$ . If  $\theta$  has a component orthogonal to z, I can choose x along that component and the supremum in the definition of  $f^*$  is  $+\infty$ . Hence, let's consider the case that  $\theta = \alpha z$ . In this case, we have

$$f^{\star}(\boldsymbol{\theta}) = \sup_{\boldsymbol{x}} \alpha \langle \boldsymbol{z}, \boldsymbol{x} \rangle - \max(1 - \langle \boldsymbol{z}, \boldsymbol{x} \rangle, 0) = \sup_{\boldsymbol{y}} \alpha u - \max(1 - u, 0).$$

If  $\alpha > 0$  or  $\alpha < -1$ , again the supremum is  $+\infty$ . Hence, we only need to consider the case that  $-1 \le \alpha \le 0$ . From a case analysis on u, it is easy to see that in this case the supremum is attained in u = 1. Putting all together, we have

$$f^{\star}(\boldsymbol{\theta}) = \begin{cases} \alpha, & \text{if } \boldsymbol{\theta} = \alpha \boldsymbol{z}, \alpha \in [-1, 0], \\ +\infty, & \text{otherwise.} \end{cases}$$

**Example 6.21** (Conjugate of squared norms). Consider the function  $f(x) = \frac{1}{2} ||x||^2$ , where  $||\cdot||$  is a norm in  $\mathbb{R}^d$ , with dual norm  $||\cdot||_{\star}$ . We can show that its conjugate is  $f^{\star}(\theta) = \frac{1}{2} ||\theta||_{\star}^2$ . From

$$\langle \boldsymbol{\theta}, \boldsymbol{x} \rangle - \frac{1}{2} \| \boldsymbol{x} \|^2 \le \| \boldsymbol{\theta} \|_{\star} \| \boldsymbol{x} \| - \frac{1}{2} \| \boldsymbol{x} \|^2$$

for all x. The right hand side is a quadratic function of ||x||, which has maximum value  $\frac{1}{2}||\theta||_{\star}^2$ . Therefore for all x, we have

$$\langle \boldsymbol{\theta}, \boldsymbol{x} \rangle - \frac{1}{2} \| \boldsymbol{x} \|^2 \le \frac{1}{2} \| \boldsymbol{\theta} \|_{\star}^2,$$

which shows that  $f^*(\theta) \leq \frac{1}{2} \|\theta\|_{\star}^2$ . To show the other inequality, let x be any vector with  $\langle \theta, x \rangle = \|\theta\|_{\star} \|x\|$ , scaled so that  $\|x\| = \|\theta\|_{\star}$ . Then we have, for this x,

$$\langle \boldsymbol{\theta}, \boldsymbol{x} \rangle - \frac{1}{2} \| \boldsymbol{x} \|^2 = \frac{1}{2} \| \boldsymbol{\theta} \|_{\star}^2,$$

which shows that  $f^*(\boldsymbol{\theta}) \geq \frac{1}{2} \|\boldsymbol{\theta}\|_{\star}^2$ .

**Example 6.22** (Young's inequality). Let p > 1 and  $f : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$  defined as  $f(x) = \frac{1}{p}x^p$ . Let's calculate the conjugate. We have

$$f^{\star}(\theta) = \sup_{x \ge 0} \theta x - \frac{1}{p} x^p$$
.

If  $\theta < 0$ , than the supremum is 0. For  $\theta \ge 0$ , by differentiation, we have that  $x^* = \theta^{\frac{1}{p-1}}$ . So, we have

$$f^{\star}(\theta) = \begin{cases} 0, & \text{if } \theta < 0, \\ \frac{p-1}{p} \theta^{\frac{p}{p-1}}, & \text{if } \theta \ge 0. \end{cases}$$

Denoting by q > 1 the positive number such that  $\frac{1}{p} + \frac{1}{q} = 1$ , we can rewrite it as

$$f^{\star}(\theta) = \begin{cases} 0, & \text{if } \theta < 0, \\ \frac{1}{q} \theta^{q}, & \text{if } \theta \ge 0. \end{cases}$$

Using the Fenchel-Young inequality, for  $x, y \ge 0$  and p, q > 1 such that 1/p + 1/q = 1, we have

$$xy \le \frac{1}{p}x^p + \frac{1}{q}y^q,$$

that is called Young's inequality.

**Example 6.23** (Conjugate of norms). *Consider the function* f(x) = ||x||, *where*  $||\cdot||$  *is a norm in*  $\mathbb{R}^d$ , *with dual norm*  $||\cdot||_{\star}$ . *Then, we have* 

$$f^{\star}(\boldsymbol{\theta}) = \sup_{\boldsymbol{x} \in \mathbb{R}^d} \langle \boldsymbol{\theta}, \boldsymbol{x} \rangle - \|\boldsymbol{x}\| \leq \sup_{\boldsymbol{x} \in \mathbb{R}^d} \|\boldsymbol{\theta}\|_{\star} \|\boldsymbol{x}\| - \|\boldsymbol{x}\| = \begin{cases} 0, & \|\boldsymbol{\theta}\|_{\star} \leq 1, \\ +\infty, & \|\boldsymbol{\theta}\|_{\star} > 1. \end{cases}$$

To show the other inequality, let x be any vector with  $\langle \theta, x \rangle = \|\theta\|_{\star} \|x\|$ , scaled so that  $\|x\| = \alpha$ . Then, we have

$$f^{\star}(\boldsymbol{\theta}) = \sup_{\boldsymbol{x} \in \mathbb{R}^d} \langle \boldsymbol{\theta}, \boldsymbol{x} \rangle - \|\boldsymbol{x}\| \ge \sup_{\alpha \in \mathbb{R}_{>0}} \alpha \|\boldsymbol{\theta}\|_{\star} - \alpha = \begin{cases} 0, & \|\boldsymbol{\theta}\|_{\star} \le 1, \\ +\infty, & \|\boldsymbol{\theta}\|_{\star} > 1. \end{cases}$$

**Lemma 6.24.** Let f be a function and let  $f^*$  be its Fenchel conjugate. For a > 0 and  $b \in \mathbb{R}$ , the Fenchel conjugate of  $h(x) = af(x) + b + \langle g, x \rangle$  is  $h^*(\theta) = af^*((\theta - g)/a) - b$ .

*Proof.* From the definition of conjugate function, we have

$$h^{\star}(\boldsymbol{\theta}) = \sup_{\boldsymbol{x} \in \mathbb{R}^d} \langle \boldsymbol{\theta} - \boldsymbol{g}, \boldsymbol{x} \rangle - af(\boldsymbol{x}) - b = -b + a \sup_{\boldsymbol{x} \in \mathbb{R}^d} \left( \left\langle \frac{\boldsymbol{\theta} - \boldsymbol{g}}{a}, \boldsymbol{x} \right\rangle - f(\boldsymbol{x}) \right) = -b + af^{\star} \left( \frac{\boldsymbol{\theta} - \boldsymbol{g}}{a} \right) . \quad \Box$$

**Lemma 6.25.** Let  $f_1$  and  $f_2$  such that  $f_1(x) \leq f_2(x)$  for all x. Then,  $f_1^{\star}(\theta) \geq f_2^{\star}(\theta)$  for all  $\theta$ .

Proof.

$$f_2^{\star}(\boldsymbol{\theta}) = \sup_{\boldsymbol{x}} \langle \boldsymbol{\theta}, \boldsymbol{x} \rangle - f_2(\boldsymbol{x}) \le \sup_{\boldsymbol{x}} \langle \boldsymbol{\theta}, \boldsymbol{x} \rangle - f_1(\boldsymbol{x}) = f_1^{\star}(\boldsymbol{\theta}).$$

**Lemma 6.26** ([Bauschke and Combettes, 2011, Example 13.7]). Let  $f : \mathbb{R} \to (-\infty, +\infty]$  even, i.e., f(x) = f(-x). Then  $(f \circ \|\cdot\|_2)^* = f^* \circ \|\cdot\|_2$ .

**Remark 6.27.** There is a tight connection between the dual function in convex optimization and the Fenchel conjugate. Indeed, let  $f: \mathbb{R}^d \to (-\infty, +\infty]$  and consider the constrained optimization problem

$$egin{array}{ll} \min & f(oldsymbol{x}) \\ s.t. & oldsymbol{A} oldsymbol{x} \leq oldsymbol{b} \\ oldsymbol{C} oldsymbol{x} = oldsymbol{d}, \end{array}$$

where the inequality is component-wise and A, C are matrices. The dual function is defined as

$$g(\lambda, \nu) = \inf_{\boldsymbol{x}} (f(\boldsymbol{x}) + \lambda^{\top} (\boldsymbol{A}\boldsymbol{x} - \boldsymbol{b}) + \nu^{\top} (\boldsymbol{C}\boldsymbol{x} - \boldsymbol{d}))$$
$$= -\boldsymbol{b}^{\top} \lambda - \boldsymbol{d}^{\top} \nu + \inf_{\boldsymbol{x}} (f(\boldsymbol{x}) + (\boldsymbol{A}^{\top} \lambda + \boldsymbol{C}^{\top} \nu)^{\top} \boldsymbol{x})$$
$$= -\boldsymbol{b}^{\top} \lambda - \boldsymbol{d}^{\top} \nu - f^{\star} (-\boldsymbol{A}^{\top} \lambda - \boldsymbol{C}^{\top} \nu).$$

For closed, convex, and proper functions, Theorem 6.16 implies that  $x \in \partial f^*(\theta)$  iff  $\theta \in \partial f(x)$ , that in words means that  $(\partial f)^{-1} = \partial f^*$  in the sense of multivalued mappings. Now, we show that for strongly convex functions the Fenchel conjugate is smooth and hence differentiable.

**Theorem 6.28** (Duality Strong Convexity/Smoothness). Let  $f: \mathbb{R}^d \to (-\infty, +\infty]$  be a proper, closed, convex function, and dom  $\partial f$  be non-empty. Then, f is  $\lambda > 0$  strongly convex w.r.t.  $\|\cdot\|$  iff  $f^*$  is  $\frac{1}{\lambda}$ -smooth w.r.t.  $\|\cdot\|_*$  on  $\mathbb{R}^d$ .

*Proof.* Let's first prove the implication from left to right. First, let's show that  $f^*$  is differentiable. Since f is proper, closed, and strongly convex, the maximizer of  $\max_{\boldsymbol{x}} \langle \boldsymbol{\theta}, \boldsymbol{x} \rangle - f(\boldsymbol{x})$  exists and it is unique by Theorem 6.9. Denote by  $\boldsymbol{x}^*$  the argmax of this expression. Hence, from Theorem 6.16, we have  $\boldsymbol{x}^* \in \partial f^*(\boldsymbol{\theta})$ . Let's now show that this is the only element in the subdifferential. Assume there exists  $\boldsymbol{x}' \in \partial f^*(\boldsymbol{\theta})$ , then from Theorem 6.16, we have  $f^*(\boldsymbol{\theta}) = \langle \boldsymbol{\theta}, \boldsymbol{x}' \rangle - f(\boldsymbol{x}')$  but from the uniqueness of the maximizer we have that  $\boldsymbol{x}^* = \boldsymbol{x}'$ .

Now, let's prove the that gradient of  $f^*$  is  $\frac{1}{\lambda}$ -Lipschitz w.r.t.  $\|\cdot\|_{\star}$ . For any  $\theta_1$  and  $\theta_2$ , set  $x_1 = \nabla f^*(\theta_1)$  and  $x_2 = \nabla f^*(\theta_2)$ . From Theorem 6.16, we have that  $\theta_1 \in \partial f(x_1)$  and  $\theta_2 \in \partial f(x_2)$ . Hence, by Lemma 4.2, we have

$$egin{aligned} f(oldsymbol{x}_2) &\geq f(oldsymbol{x}_1) + \langle oldsymbol{ heta}_1, oldsymbol{x}_2 - oldsymbol{x}_1 
angle + rac{\lambda}{2} \|oldsymbol{x}_1 - oldsymbol{x}_2\|^2, \ f(oldsymbol{x}_1) &\geq f(oldsymbol{x}_2) + \langle oldsymbol{ heta}_2, oldsymbol{x}_1 - oldsymbol{x}_2 
angle + rac{\lambda}{2} \|oldsymbol{x}_1 - oldsymbol{x}_2\|^2. \end{aligned}$$

Summing these two inequalities, we have

$$\|m{ heta}_1 - m{ heta}_2\|_{\star} \|m{x}_1 - m{x}_2\| \ge \langle m{ heta}_2 - m{ heta}_1, m{x}_1 - m{x}_2 
angle \ge \lambda \|m{x}_1 - m{x}_2\|^2,$$

where in the first inequality we used the definition of dual norms. Solving the inequality we get that

$$\|\boldsymbol{\theta}_1 - \boldsymbol{\theta}_2\|_{\star} \ge \lambda \|\boldsymbol{x}_1 - \boldsymbol{x}_2\| = \lambda \|\nabla f^{\star}(\boldsymbol{\theta}_1) - \nabla f^{\star}(\boldsymbol{\theta}_2)\|$$
.

Let's now prove the other direction. Assume that  $f^{\star}$  is  $\frac{1}{\lambda}$ -smooth w.r.t.  $\|\cdot\|_{\star}$  on  $\mathbb{R}^d$ . Set  $\mathbf{y} \in \operatorname{dom} \partial f$  and  $\mathbf{u} \in \partial f(\mathbf{y})$ . Hence, by Theorem 6.16 and the differentiability of  $f^{\star}$ , we also have  $\mathbf{y} = \nabla f^{\star}(\mathbf{u})$ . Define  $\phi(\theta) := f^{\star}(\theta + \mathbf{u}) - f^{\star}(\mathbf{u}) - \langle \theta, \nabla f^{\star}(\mathbf{u}) \rangle$ . From the  $\frac{1}{\lambda}$ -smoothness and Lemma 4.22, we have  $\phi(\theta) \leq \frac{1}{2\lambda} \|\theta\|_{\star}^2$ . From Lemma 6.25 and Example 6.21, we have that  $\phi^{\star}(\mathbf{x}) \geq \frac{\lambda}{2} \|\mathbf{x}\|^2$ . Let's now calculate  $\phi^{\star}(\mathbf{x})$ .

$$\phi^{\star}(\boldsymbol{x}) = \sup_{\boldsymbol{\theta}} \langle \boldsymbol{\theta}, \boldsymbol{x} \rangle - f^{\star}(\boldsymbol{\theta} + \boldsymbol{u}) + f^{\star}(\boldsymbol{u}) + \langle \boldsymbol{\theta}, \nabla f^{\star}(\boldsymbol{u}) \rangle$$

$$= f^{\star}(\boldsymbol{u}) - \langle \boldsymbol{u}, \boldsymbol{x} + \nabla f^{\star}(\boldsymbol{u}) \rangle + \sup_{\boldsymbol{v}} \langle \boldsymbol{v}, \boldsymbol{x} + \nabla f^{\star}(\boldsymbol{u}) \rangle - f^{\star}(\boldsymbol{v})$$

$$= f^{\star}(\boldsymbol{u}) - \langle \boldsymbol{u}, \boldsymbol{x} + \nabla f^{\star}(\boldsymbol{u}) \rangle + f(\boldsymbol{x} + \nabla f^{\star}(\boldsymbol{u}))$$

$$= -\langle \boldsymbol{u}, \boldsymbol{x} \rangle - f(\nabla f^{\star}(\boldsymbol{u})) + f(\boldsymbol{x} + \nabla f^{\star}(\boldsymbol{u})),$$

where we used Theorem 6.15 in the third equality and Theorem 6.16 in the last one. Putting all together, we have

$$f(x + y) - f(y) - \langle u, x \rangle \ge \frac{\lambda}{2} ||x||^2, \ \forall u \in \partial f(y).$$

We will also use the following theorem on the first-order optimality condition.

**Theorem 6.29.** Let  $f: \mathbb{R}^d \to (-\infty, +\infty]$  proper. Then  $\mathbf{x}^* \in \operatorname{argmin}_{\mathbf{x} \in \mathbb{R}^d} f(\mathbf{x})$  iff  $\mathbf{0} \in \partial f(\mathbf{x}^*)$ .

Proof. We have that

$$m{x}^\star \in \operatorname*{argmin}_{m{x} \in \mathbb{R}^d} \ f(m{x}) \Leftrightarrow orall m{y} \in \mathbb{R}^d, \ f(m{y}) \geq f(m{x}^\star) = f(m{x}^\star) + \langle m{0}, m{y} - m{x}^\star \rangle \Leftrightarrow m{0} \in \partial f(m{x}^\star) \ .$$

#### 6.4.2 The "Mirror" Interpretation

Here, we explain the "mirror" interpretation of OMD, using the following Theorem.

**Theorem 6.30.** Let  $B_{\psi}$  the Bregman divergence w.r.t.  $\psi : \mathcal{X} \to \mathbb{R}$ , where  $\psi$  is  $\lambda > 0$  strongly convex and closed. Let  $\mathcal{V} \subset \mathcal{X}$  a non-empty closed convex set and  $\mathbf{x}_t \in \mathcal{V}$ . Define

$$egin{aligned} oldsymbol{x}_{t+1} = & & rgmin_{oldsymbol{x} \in \mathcal{V}} \left\langle oldsymbol{g}_t, oldsymbol{x} 
ight
angle + rac{1}{\eta_t} B_{\psi}(oldsymbol{x}; oldsymbol{x}_t), \end{aligned}$$

and assume  $\psi$  to be differentiable in  $\mathbf{x}_t$  and  $\mathbf{x}_{t+1}$ . Then, for any  $\mathbf{g}_t \in \mathbb{R}^d$ , we have

$$\boldsymbol{x}_{t+1} = \nabla \psi_{\mathcal{V}}^{\star} (\nabla \psi(\boldsymbol{x}_t) - \eta_t \boldsymbol{q}_t), \tag{6.8}$$

where  $\psi_{\mathcal{V}}$  the restriction of  $\psi$  to  $\mathcal{V}$ , that is  $\psi_{\mathcal{V}} := \psi + i_{\mathcal{V}}$ .

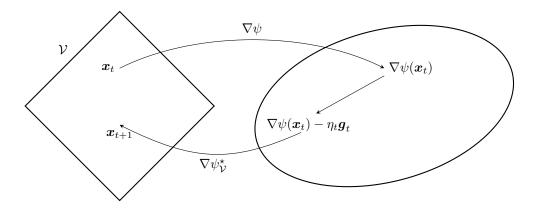

Figure 6.5: OMD update in terms of duality mappings.

Proof. We have that

$$\begin{aligned} \boldsymbol{x}_{t+1} &= \underset{\boldsymbol{x} \in \mathcal{V}}{\operatorname{argmin}} \ \langle \boldsymbol{g}_t, \boldsymbol{x} \rangle + \frac{1}{\eta_t} B_{\psi}(\boldsymbol{x}; \boldsymbol{x}_t) \\ &= \underset{\boldsymbol{x} \in \mathcal{V}}{\operatorname{argmin}} \ \eta_t \langle \boldsymbol{g}_t, \boldsymbol{x} \rangle + B_{\psi}(\boldsymbol{x}; \boldsymbol{x}_t) \\ &= \underset{\boldsymbol{x} \in \mathcal{V}}{\operatorname{argmin}} \ \eta_t \langle \boldsymbol{g}_t, \boldsymbol{x} \rangle + \psi(\boldsymbol{x}) - \psi(\boldsymbol{x}_t) - \langle \nabla \psi(\boldsymbol{x}_t), \boldsymbol{x} - \boldsymbol{x}_t \rangle \\ &= \underset{\boldsymbol{x} \in \mathcal{V}}{\operatorname{argmin}} \ \langle \eta_t \boldsymbol{g}_t - \nabla \psi(\boldsymbol{x}_t), \boldsymbol{x} \rangle + \psi(\boldsymbol{x}) \ . \end{aligned}$$

Now, we use the first-order optimality condition in Theorem 6.29, to have

$$\mathbf{0} \in \eta_t \mathbf{g}_t + \nabla \psi(\mathbf{x}_{t+1}) - \nabla \psi(\mathbf{x}_t) + \partial i_{\mathcal{V}}(\mathbf{x}_{t+1}),$$

that is

$$\nabla \psi(\boldsymbol{x}_t) - \eta_t \boldsymbol{g}_t \in (\nabla \psi + \partial i_{\mathcal{V}})(\boldsymbol{x}_{t+1}) \subseteq \partial \psi_{\mathcal{V}}(\boldsymbol{x}_{t+1}),$$

where in the last inclusion we used Theorem 2.22. Hence, from Theorem 6.16, we have

$$\boldsymbol{x}_{t+1} \in \partial \psi_{\mathcal{V}}^{\star}(\nabla \psi(\boldsymbol{x}_t) - \eta_t \boldsymbol{g}_t)$$
.

Using that fact that  $\psi_{\mathcal{V}} := \psi + i_{\mathcal{V}}$  is  $\lambda$ -strongly convex, proper, and closed, from Theorem 6.28 we have that  $\partial \psi_{\mathcal{V}}^{\star} = \{\nabla \psi_{\mathcal{V}}^{\star}\}$ . Hence,

$$\boldsymbol{x}_{t+1} = \nabla \psi_{\mathcal{V}}^{\star} (\nabla \psi(\boldsymbol{x}_t) - \eta_t \boldsymbol{g}_t) .$$

Let's explain what this theorem says. We said that Online Mirror Descent extends the Online Subgradient Descent method to non-Euclidean norms. Hence, the regret bound we proved contains dual norms, that measure the iterate and the gradients. We also said that it makes sense to use a dual norm to measure a gradient, because it is a natural way to measure how "big" is the linear functional  $x \to \langle \nabla f(y), x \rangle$ . In a more correct way, gradients actually live in the *dual space*, that is in a different space of the predictions  $x_t$ . Hence, we cannot sum iterates and gradients together, in the same way in which we cannot sum pears and apples together. So, why we were doing it in OSD? The reason is that in that case the dual space coincides with the primal space. But, it is a very particular case due to the fact that we used the  $L_2$  norm. Instead, in the general case, iterates and gradients are in two different spaces.

So, in OMD we need a way to go from one space to the other. And this is exactly the role of  $\nabla \psi$  and  $\nabla \psi_{\mathcal{V}}^{\star}$ , that are called *duality mappings*. We can now understand that the theorem tells us that OMD takes the primal vector  $\boldsymbol{x}_t$ , transforms it into a dual vector through  $\nabla \psi$ , does a subgradient descent step in the dual space, and finally transforms the vector back to the primal space through  $\nabla \psi_{\mathcal{V}}^{\star}$ . This reasoning is summarized in Figure 6.5.

**Example 6.31.** Let  $\psi : \mathbb{R}^d \to \mathbb{R}$  equal to  $\psi(x) = \frac{1}{2} ||x||_2^2$  and  $\mathcal{V} = \{x \in \mathbb{R}^d : ||x||_2 \le 1\}$ . Define  $\psi_{\mathcal{V}} = \psi + i_{\mathcal{V}}$ . Then,

$$\psi_{\mathcal{V}}^{\star}(\boldsymbol{\theta}) = \sup_{\boldsymbol{x} \in \mathcal{V}} \langle \boldsymbol{\theta}, \boldsymbol{x} \rangle - \frac{1}{2} \|\boldsymbol{x}\|_{2}^{2}$$

First of all, if  $\theta = 0$  we have that  $\psi_{\mathcal{V}}^{\star}(\theta) = 0$ . So, in the following we assume  $\theta \neq 0$ . Now for any  $x \in \mathcal{V}$  there exist q and  $\alpha$  such that  $x = \alpha \frac{\theta}{\|\theta\|_2} + q$  and  $\langle q, \theta \rangle = 0$ . Hence, we have

$$\sup_{\boldsymbol{x} \in \mathcal{V}} \langle \boldsymbol{\theta}, \boldsymbol{x} \rangle - \frac{1}{2} \|\boldsymbol{x}\|_2^2 = \sup_{\alpha, \boldsymbol{q} : \alpha \frac{\boldsymbol{\theta}}{\|\boldsymbol{\theta}\|_2} + \boldsymbol{q} \in \mathcal{V}, \langle \boldsymbol{q}, \boldsymbol{\theta} \rangle = 0} \alpha \|\boldsymbol{\theta}\|_2 - \frac{\alpha^2}{2} - \frac{1}{2} \|\boldsymbol{q}\|_2^2 = \sup_{-1 \le \alpha \le 1} \alpha \|\boldsymbol{\theta}\|_2 - \frac{\alpha^2}{2}.$$

Solving the constrained optimization problem, we have  $\alpha^* = \min(1, \|\boldsymbol{\theta}\|_2)$ . Hence, we have

$$\psi_{\mathcal{V}}^{\star}(\boldsymbol{\theta}) = \begin{cases} \frac{1}{2} \|\boldsymbol{\theta}\|_{2}^{2}, & \|\boldsymbol{\theta}\|_{2} \leq 1 \\ \|\boldsymbol{\theta}\|_{2} - \frac{1}{2}, & \|\boldsymbol{\theta}\|_{2} > 1 \end{cases},$$

that is finite everywhere and differentiable. So, we have  $abla\psi(m{x})=m{x}$  and

$$abla \psi_{\mathcal{V}}^{\star}(oldsymbol{ heta}) = egin{cases} oldsymbol{ heta}, & \|oldsymbol{ heta}\|_2 \leq 1 \ rac{oldsymbol{ heta}}{\|oldsymbol{ heta}\|_2}, & \|oldsymbol{ heta}\|_2 > 1 \end{cases} = \Pi_{\mathcal{V}}(oldsymbol{ heta}) \; .$$

So, using (6.8), we obtain exactly the update of projected online subgradient descent.

## 6.4.3 Yet Another Way to Write the Online Mirror Descent Update

There exists yet another way to write the update of OMD. This third method uses the concept of *Bregman projections*. Extending the definition of Euclidean projections, we can define the projection with respect to a Bregman divergence. Let  $\Pi_{\mathcal{V},\psi}$  be defined by

$$\Pi_{\mathcal{V},\psi}(\boldsymbol{x}) = \underset{\boldsymbol{y} \in \mathcal{V}}{\operatorname{argmin}} \ B_{\psi}(\boldsymbol{y}; \boldsymbol{x}) \ .$$

In the online learning literature, the OMD algorithm is typically presented with a two step update: first, solving the argmin over the entire space and then projecting back over V with respect to the Bregman divergence. In the following, we show that most of the time the two-step update is equivalent to the one-step update in (6.8).

First, we prove a general theorem that allows to break the constrained minimization of functions in the minimization over the entire space plus and Bregman projection step.

**Theorem 6.32.** Let  $f: \mathbb{R}^d \to (-\infty, +\infty]$  proper, closed, strictly convex, and differentiable in int dom f. Also, let  $\mathcal{V} \subset \mathbb{R}^d$  a non-empty, closed convex set with  $\mathcal{V} \cap \text{dom } f \neq \{\}$  and assume that  $\tilde{\boldsymbol{y}} = \operatorname{argmin}_{\boldsymbol{z} \in \mathbb{R}^d} f(\boldsymbol{z})$  exists and  $\tilde{\boldsymbol{y}} \in \text{int dom } f$ . Denote by  $\boldsymbol{y}' = \operatorname{argmin}_{\boldsymbol{z} \in \mathcal{V}} B_f(\boldsymbol{z}; \tilde{\boldsymbol{y}})$ . Then, the following hold:

1.  $y = \operatorname{argmin}_{z \in \mathcal{V}} f(z)$  exists and is unique.

2. 
$$y = y'$$
.

*Proof.* For the first point, from [Bauschke and Combettes, 2011, Proposition 11.12] and the existence of  $\tilde{y}$ , we have that f is coercive. So, from Bauschke and Combettes [2011, Proposition 11.14], the minimizer of f in V exists. Given that f is strictly convex, the minimizer must be unique too.

For the second point, from the definition of y, we have  $f(y) \leq f(y')$ . On the other hand, from the first-order optimality condition, we have  $\nabla f(\tilde{y}) = 0$ . So, we have

$$f(\mathbf{y}') - f(\tilde{\mathbf{y}}) = B_f(\mathbf{y}'; \tilde{\mathbf{y}}) \le B_f(\mathbf{y}; \tilde{\mathbf{y}}) = f(\mathbf{y}) - f(\tilde{\mathbf{y}}),$$

that is  $f(y') \le f(y)$ . Given that f is strictly convex, y' = y.

Now, note that, if  $\tilde{\psi}(x) = \psi(x) + \langle g, x \rangle$ , then

$$\begin{split} B_{\tilde{\psi}}(\boldsymbol{x};\boldsymbol{y}) &= \tilde{\psi}(\boldsymbol{x}) - \tilde{\psi}(\boldsymbol{y}) - \langle \nabla \tilde{\psi}(\boldsymbol{y}), \boldsymbol{x} - \boldsymbol{y} \rangle \\ &= \psi(\boldsymbol{x}) - \psi(\boldsymbol{y}) - \langle \boldsymbol{g} + \nabla \psi(\boldsymbol{y}), \boldsymbol{x} - \boldsymbol{y} \rangle + \langle \boldsymbol{g}, \boldsymbol{x} - \boldsymbol{y} \rangle \\ &= \psi(\boldsymbol{x}) - \psi(\boldsymbol{y}) - \langle \nabla \psi(\boldsymbol{y}), \boldsymbol{x} - \boldsymbol{y} \rangle \\ &= B_{\psi}(\boldsymbol{x}; \boldsymbol{y}) \; . \end{split}$$

Now, define  $f(x) = \langle \eta_t g_t, x \rangle + B_{\psi}(x; x_t)$ , so that  $f(x) = \psi(x) + \langle z, x \rangle + K$  for some  $K \in \mathbb{R}$  and  $z \in \mathbb{R}^d$ . This implies that  $B_f(x; y) = B_{\psi}(x; y)$ . Hence, under the assumption of the above theorem, we have that  $x_{t+1} = \operatorname{argmin}_{x \in \mathcal{V}} \langle g_t, x \rangle + \frac{1}{n_t} B_{\psi}(x; x_t)$  is equivalent to

$$\tilde{\boldsymbol{x}}_{t+1} = \underset{\boldsymbol{x} \in \mathbb{R}^d}{\operatorname{argmin}} \langle \eta_t \boldsymbol{g}_t, \boldsymbol{x} \rangle + B_{\psi}(\boldsymbol{x}; \boldsymbol{x}_t), 
\boldsymbol{x}_{t+1} = \underset{\boldsymbol{x} \in \mathcal{V}}{\operatorname{argmin}} B_{\psi}(\boldsymbol{x}; \tilde{\boldsymbol{x}}_{t+1}).$$

The advantage of this update is that sometimes it gives two easier problems to solve rather than a single difficult one.

## 6.5 OMD Regret Bound using Local Norms

In Lemma 6.10, strong convexity basically tells us some minimum curvature in all the directions, that allows to upper bound the difference between  $x_t$  and  $x_{t+1}$ . However, it turns out that we can still get a meaningful regret upper bound without this assumption. In particular, we can get an interesting expression for the regret that involves the use of **local norms**. We will use these ideas in the section on Multi-armed Bandits (Chapter 11).

**Lemma 6.33.** Let  $B_{\psi}$  the Bregman divergence w.r.t.  $\psi: \mathcal{X} \to \mathbb{R}$  and assume  $\psi$  twice differentiable and with the Hessian positive definite in the interior of its domain. Let  $\mathcal{V} \subseteq \mathcal{X}$  a non-empty closed convex set. Assume (6.5) or (6.6) to hold. Define  $\|\mathbf{x}\|_{\mathbf{A}} := \sqrt{\mathbf{x}^{\top}\mathbf{A}\mathbf{x}}$ . Also, with the notation in Algorithm 6.1, assume  $\mathbf{x}_{t+1}$  and  $\tilde{\mathbf{x}}_{t+1} \in \operatorname{argmin}_{\mathbf{x} \in \mathcal{X}} \langle \mathbf{g}_t, \mathbf{x} \rangle + \frac{1}{\eta_t} B_{\psi}(\mathbf{x}; \mathbf{x}_t)$  exist. Then,  $\forall \mathbf{u} \in \mathcal{V}$ , there exists  $\mathbf{z}_t$  on the line segments between  $\mathbf{x}_t$  and  $\tilde{\mathbf{x}}_{t+1}$ , and  $\mathbf{z}'_t$  on the line segments between  $\mathbf{x}_t$  and  $\tilde{\mathbf{x}}_{t+1}$ , such that the following inequality holds

$$\eta_t(\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) \le \eta_t(\boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{u}) \le B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_t) - B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_{t+1}) + \frac{\eta_t^2}{2} \min\left(\|\boldsymbol{g}_t\|_{(\nabla^2 \psi(\boldsymbol{z}_t))^{-1}}^2, \|\boldsymbol{g}_t\|_{(\nabla^2 \psi(\boldsymbol{z}_t'))^{-1}}^2\right).$$

*Proof.* First of all, from Theorem 6.8,  $x_t$  and  $\tilde{x}_t$  are in the interior of  $\mathcal{X}$  for all  $t \geq 1$ . Then, from Lemma 6.10, we have

$$\langle \eta_t \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{u} \rangle \leq B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_t) - B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_{t+1}) - B_{\psi}(\boldsymbol{x}_{t+1}; \boldsymbol{x}_t) + \langle \eta_t \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{x}_{t+1} \rangle. \tag{6.9}$$

From the Taylor's theorem, we have said that  $B_{\psi}(\boldsymbol{x}_{t+1}; \boldsymbol{x}_t) = \frac{1}{2}(\boldsymbol{x}_{t+1} - \boldsymbol{x}_t)^{\top} \nabla^2 \psi(\boldsymbol{z}_t) (\boldsymbol{x}_{t+1} - \boldsymbol{x}_t)$  for some  $\boldsymbol{z}_t$  on the line segment between  $\boldsymbol{x}_t$  and  $\boldsymbol{x}_{t+1}$ . Observe that this is  $\frac{1}{2} \| \boldsymbol{x}_{t+1} - \boldsymbol{x}_t \|_{\nabla^2 \psi(\boldsymbol{z}_t)}^2$  and it is indeed a norm because we assumed the Hessian of  $\psi$  to be positive definite. Hence, by Fenchel-Young inequality and Examples 4.18 and 6.21, we have

$$\langle \eta_{t} \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{x}_{t+1} \rangle - B_{\psi}(\boldsymbol{x}_{t+1}; \boldsymbol{x}_{t}) \leq \frac{\eta_{t}^{2}}{2} \|\boldsymbol{g}_{t}\|_{(\nabla^{2}\psi(\boldsymbol{z}_{t}))^{-1}}^{2} + \frac{1}{2} (\boldsymbol{x}_{t+1} - \boldsymbol{x}_{t})^{\top} \nabla^{2}\psi(\boldsymbol{z}_{t}) (\boldsymbol{x}_{t+1} - \boldsymbol{x}_{t}) - B_{\psi}(\boldsymbol{x}_{t+1}; \boldsymbol{x}_{t})$$

$$= \frac{\eta_{t}^{2}}{2} \|\boldsymbol{g}_{t}\|_{(\nabla^{2}\psi(\boldsymbol{z}_{t}))^{-1}}^{2},$$

that gives the first term in the minimum.

For the second term in the minimum, we instead observe that

$$\langle \eta_t \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{x}_{t+1} \rangle - B_{\psi}(\boldsymbol{x}_{t+1}; \boldsymbol{x}_t) \leq \max_{\boldsymbol{x} \in \mathcal{X}} \langle \eta_t \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{x} \rangle - B_{\psi}(\boldsymbol{x}; \boldsymbol{x}_t) = \langle \eta_t \boldsymbol{g}_t, \boldsymbol{x}_t - \tilde{\boldsymbol{x}}_{t+1} \rangle - B_{\psi}(\tilde{\boldsymbol{x}}_{t+1}; \boldsymbol{x}_t) .$$

Then, we proceed as in the first bound.

Despite the apparent more difficult formulation, the second term in the minimum is often easier to use, especially in constrained settings because  $\tilde{x}_{t+1}$  is defined over  $\mathcal{X}$  rather than over  $\mathcal{V}$ . Also, under the assumptions of Theorem 6.32, it is easy to recognize that  $x_{t+1}$  is the Bregman projection of  $\tilde{x}_{t+1}$  onto  $\mathcal{V}$ .

## **Example of OMD: Exponentiated Gradient**

#### Algorithm 6.2 Exponentiated Gradient

```
Require: \eta > 0
```

- 1: Set  $x_1 = [1/d, \dots, 1/d]$
- 2: for t = 1 to T do
- Output  $oldsymbol{x}_t \in \Delta^{d-1}$
- Pay  $\ell_t(x_t)$  for  $\ell_t: \Delta^{d-1} \to \mathbb{R}$  subdifferentiable in  $\Delta^{d-1}$
- Set  $\boldsymbol{g}_t \in \partial \ell_t(\boldsymbol{x}_t)$   $x_{t+1,j} = \frac{x_{t,j} \exp(-\eta g_{t,j})}{\sum_{i=1}^{d} x_{t,i} \exp(-\eta g_{t,i})}, \ j = 1, \dots, d$

Let  $\Delta^{d-1}=\{x\in\mathbb{R}^d:x_i\geq 0,\|x\|_1=1\}$  the probability simplex and set  $\mathcal{V}=\Delta^{d-1}$ . So, in words, we want to output discrete probability distributions over  $\mathbb{R}^d$ . Also, let  $\mathcal{X}=\mathbb{R}^d_{\geq 0}$  and  $\psi(x):X\to\mathbb{R}$  defined as  $\psi(x) = \sum_{i=1}^{d} x_i \ln x_i$ , where we define  $0 \ln(0) = 0$ . Note that the restriction of  $\psi$  to  $\mathcal{V}$  is the negative entropy of the discrete distributions in  $\Delta^{d-1}$ . It is possible to verify that  $\psi$  satisfies the first condition in Theorem 6.8, hence the update is well defined.

The Fenchel conjugate  $\psi_{\mathcal{V}}^{\star}(\boldsymbol{\theta})$  is defined as

$$\psi_{\mathcal{V}}^{\star}(\boldsymbol{\theta}) = \sup_{\boldsymbol{x} \in \mathcal{V}} \langle \boldsymbol{\theta}, \boldsymbol{x} \rangle - \psi(\boldsymbol{x}) = \sup_{\boldsymbol{x} \in \mathcal{V}} \langle \boldsymbol{\theta}, \boldsymbol{x} \rangle - \sum_{i=1}^{d} x_i \ln x_i.$$

It is a constrained optimization problem, we could solve it using the KKT conditions. However, there is a simpler way to do it: We will remove the probability simplex constraint rephrasing the problem over d-1 variables. In fact, the maximization problem is equivalent to

$$\min_{\boldsymbol{x} \in \mathbb{R}^{d-1}} \sum_{i=1}^{d-1} x_i \ln x_i + \left(1 - \sum_{i=1}^{d-1} x_i\right) \ln \left(1 - \sum_{i=1}^{d-1} x_i\right) - \sum_{i=1}^{d-1} \theta_i x_i - \theta_d \left(1 - \sum_{i=1}^{d-1} x_i\right) .$$

Note that the constraint on  $x_1, \ldots, x_{d-1}$  and  $1 - \sum_{i=1}^{d-1} x_i$  to be non-negative is enforced by the domain of the logarithm. This is now an unconstrained concave optimization problem, so we can solve it equating the gradient of the objective function to zero. Hence, we have

$$\ln \frac{x_i}{1 - \sum_{j=1}^{d-1} x_j} = \theta_i - \theta_d, \ i = 1, \dots, d-1.$$

That is

$$x_i = \exp(\theta_i - \theta_d) \left( 1 - \sum_{j=1}^{d-1} x_j \right), \ i = 1, \dots, d-1.$$
 (6.10)

Summing this equality over  $i = 1, \dots, d - 1$ , we obtain

$$\sum_{i=1}^{d-1} x_i = \sum_{i=1}^{d-1} \exp(\theta_i - \theta_d) \left( 1 - \sum_{j=1}^{d-1} x_j \right)$$

that can be solved to obtain

$$1 - \sum_{j=1}^{d-1} x_i = \frac{1}{1 + \sum_{j=1}^{d-1} \exp(\theta_j - \theta_d)}.$$

Substituting it back in (6.10), we have

$$x_{i} = \frac{\exp(\theta_{i} - \theta_{d})}{1 + \sum_{j=1}^{d-1} \exp(\theta_{j} - \theta_{d})} = \frac{\exp(\theta_{i})}{\sum_{j=1}^{d} \exp(\theta_{j})}, i = 1, \dots, d.$$
 (6.11)

Denoting with  $\alpha = \sum_{i=1}^{d} \exp(\theta_i)$ , and substituting in the definition of the conjugate function we get

$$\psi_{\mathcal{V}}^{\star}(\boldsymbol{\theta}) = \sum_{i=1}^{d} \left( \frac{1}{\alpha} \theta_{i} \exp(\theta_{i}) - \frac{1}{\alpha} \exp(\theta_{i}) (\theta_{i} - \ln(\alpha)) \right) = \ln(\alpha) \frac{1}{\alpha} \sum_{i=1}^{d} \exp(\theta_{i}) = \ln(\alpha) = \ln\left(\sum_{i=1}^{d} \exp(\theta_{i})\right).$$

We also have  $(\nabla \psi_{\mathcal{V}}^{\star}(\boldsymbol{\theta}))_j = \frac{\exp(\theta_j)}{\sum_{i=1}^d \exp(\theta_i)}$  and  $(\nabla \psi(\boldsymbol{x}))_j = \ln(x_j) + 1$  for  $\boldsymbol{x} \in \mathbb{R}^d_{>0}$ . Note that we could have also derived the gradient of  $\psi_{\mathcal{V}}^{\star}$  directly from (6.11), using Theorem 6.16.

Putting all together, we have the online mirror descent update rule for entropic distance generating function.

$$x_{t+1,j} = \frac{\exp(\ln x_{t,j} + 1 - \eta_t g_{t,j})}{\sum_{i=1}^d \exp(\ln x_{t,i} + 1 - \eta_t g_{t,i})} = \frac{x_{t,j} \exp(-\eta_t g_{t,j})}{\sum_{i=1}^d x_{t,i} \exp(-\eta_t g_{t,i})}.$$

The algorithm is summarized in Algorithm 6.2. This algorithm is called *Exponentiated Gradient* (EG) because in the update rule we take the component-wise exponent of the (sub)gradient vector.

Let's take a look at the regret bound we get. From Example 6.6, for all  $x \in \Delta^{d-1}$  and  $y \in \{x \in \mathbb{R}^d : x_i > 0, \|x\|_1 = 1\}$ , we have  $\mathrm{KL}(x;y) := B_{\psi}(x;y) = \sum_{i=1}^d x_i \ln \frac{x_i}{y_i}$ , that is the KL divergence between the discrete distributions x and y. Now, we prove the strong convexity of  $\psi$ .

**Lemma 6.34.**  $\psi(x) = \sum_{i=1}^{d} x_i \ln x_i$  is 1-strongly convex with respect to the  $L_1$  norm over the set  $K = \{x \in \mathbb{R}^d : x_i > 0, ||x||_1 = 1\}$ .

*Proof.* The statement is implied by Pinsker's inequality, but here we give a short and direct proof from Beck and Teboulle [2003, Proposition 5.1].

Let  $\phi(u)=(u-1)\ln u-\frac{2(u-1)^2}{u+1}$  for u>0. Observe that  $\phi''(u)>0$  for u>0 so the function is convex. Moreover,  $\phi(1)=\phi'(1)=0$ . So, we have  $\phi(u)\geq\phi(1)+\phi'(1)(x-1)=0$  for all u>0.

Using this inequality, we have

$$\langle \nabla \psi(\boldsymbol{x}) - \nabla \psi(\boldsymbol{y}), \boldsymbol{x} - \boldsymbol{y} \rangle = \sum_{i=1}^{d} (x_i - y_i) \ln \frac{x_i}{y_i} = \sum_{i=1}^{d} y_i \left( \frac{x_i}{y_i} - 1 \right) \ln \frac{x_i}{y_i} \ge \sum_{i=1}^{d} \frac{2(x_i - y_i)^2}{x_i + y_i}$$
$$= \sum_{i=1}^{d} \frac{x_i + y_i}{2} \left( \frac{|x_i - y_i|}{\frac{x_i + y_i}{2}} \right)^2 \ge \left( \sum_{i=1}^{d} \frac{x_i + y_i}{2} \frac{|x_i - y_i|}{\frac{x_i + y_i}{2}} \right)^2 = \|\boldsymbol{x} - \boldsymbol{y}\|_1^2,$$

where in the last inequality we used Jensen's inequality because  $\frac{x+y}{2} \in K$ . Using Theorem 4.3 completes the proof.

Another thing to decide is the initial point  $x_1$ . A reasonable choice is to set  $x_1$  to be the minimizer of  $\psi$  in  $\mathcal{V}$ . Hence, we set  $x_1 = [1/d, \dots, 1/d] \in \mathbb{R}^d$ , because the uniform distribution minimizes the negative entropy. Given that the minimizer is in the interior of  $\mathcal{X}$ ,  $\nabla \psi(x_1) = \mathbf{0}$  and  $B_{\psi}(u; x_1)$  is equal to  $\psi(u) - \min_{x \in \mathcal{V}} \psi(x)$ . So, we have  $B_{\psi}(u; x_1) = \sum_{i=1}^d u_i \ln u_i + \ln d \leq \ln d$ .

Putting all together, we have

$$\sum_{t=1}^{T} (\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) \leq \frac{\ln d}{\eta} + \frac{\eta}{2} \sum_{t=1}^{T} \|\boldsymbol{g}_t\|_{\infty}^2.$$

Assuming  $\|g_t\|_{\infty} \leq L_{\infty}$ , we can set  $\eta = \sqrt{\frac{2 \ln d}{L_{\infty}^2 T}}$ , to obtain that a regret of  $\sqrt{2} L_{\infty} \sqrt{T \ln d}$ .

**Remark 6.35.** Note that the time-varying version of OMD with entropic distance generating function would give rise to a vacuous bound, can you see why? In the next chapter, we will see how FTRL overcomes this issue using a time-varying regularizer rather than a time-varying learning rate.

We can also get a *tighter* bound using the local norms. Let's use the additional assumption that  $g_{t,i} \geq 0$ , for all  $t=1,\ldots,T$  and  $i=1,\ldots,d$ . Summing the inequality of Lemma 6.33 from t=1 to T, we have for all  $u\in\mathcal{V}$  that

$$\sum_{t=1}^{T} \ell_t(\boldsymbol{x}_t) - \sum_{t=1}^{T} \ell(\boldsymbol{u}) \le \frac{\ln d}{\eta} + \frac{\eta}{2} \sum_{t=1}^{T} \|\boldsymbol{g}_t\|_{(\nabla^2 \psi(\boldsymbol{z}_t'))^{-1}}^2,$$

where  $z_t'$  is on the line segment between  $x_t$  and  $\tilde{x}_{t+1}$ . In this case, it is easy to calculate  $\tilde{x}_{t+1,i}$  as  $x_{t,i} \exp(-\eta g_{t,i})$  for  $i=1,\ldots,d$ . Moreover,  $\nabla^2 \psi(z_t')$  is a diagonal matrix whose elements on the diagonal are  $\frac{1}{z_{t,i}'}$ ,  $i=1,\ldots,d$ . Hence, we have that

$$\|\boldsymbol{g}_t\|_{(\nabla^2 \psi(\boldsymbol{z}_t'))^{-1}}^2 = \sum_{i=1}^d g_{t,i}^2 z_{t,i}' \le \sum_{i=1}^d g_{t,i}^2 x_{t,i} .$$

Putting all together, the final bound would be

$$\sum_{t=1}^{T} \ell_t(\boldsymbol{x}_t) - \sum_{t=1}^{T} \ell(\boldsymbol{u}) \le \frac{\ln d}{\eta} + \frac{\eta}{2} \sum_{t=1}^{T} \sum_{i=1}^{d} g_{t,i}^2 x_{t,i}.$$

This is indeed a tighter bound because  $\sum_{i=1}^d g_{t,i}^2 x_{t,i} \leq \|\boldsymbol{g}_t\|_{\infty}^2$ . How would Online Subgradient Descent (OSD) work on the same problem? First, it is important to realize that nothing prevents us to use OSD on this problem. We just have to implement the Euclidean projection onto the probability simplex, that does not have a closed formula but it can be implemented in  $\mathcal{O}(d \ln d)$  time, see Condat [2016]. The regret bound we would get from OSD is

$$\sum_{t=1}^{T} (\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) \leq \frac{2}{\eta} + \frac{\eta}{2} \sum_{t=1}^{T} \|\boldsymbol{g}_t\|_2^2 \leq \frac{2}{\eta} + \frac{\eta}{2} T L_2^2,$$

where  $L_2 \ge \|\boldsymbol{g}_t\|_2$  for all t. Optimally tuning the learning rate, we get

$$\sum_{t=1}^{T} (\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) \le 2L_2 \sqrt{T} .$$

To compare it with the bound the bound of EG, it is sufficient to observe that

$$\frac{1}{\sqrt{d}} \|\boldsymbol{g}_t\|_2 \le \|\boldsymbol{g}_t\|_{\infty} \le \|\boldsymbol{g}_t\|_2,$$

and the inequalities are tight. Hence, ignoring the numerical constants, the bound of EG is between  $\sqrt{\frac{\ln d}{d}}$  and  $\sqrt{\ln d}$ times the one of OSD, depending on the structure of the subgradients  $q_t$ . Hence, in a worst case sense with respect to the infinity norm of the subgradients  $g_t$ , using an entropic distance generating function can transform a dependency on the dimension from  $\sqrt{d}$  to  $\sqrt{\ln d}$  for Online Convex Optimization (OCO) over the probability simplex. So, as we already saw analyzing AdaGrad, the shape of the domain and the structure of the subgradients are the important ingredients when we move from the Euclidean norm to other norms.

#### **6.7** Example of OMD: p-norm Algorithms

Consider the distance generating function  $\psi(x) = \frac{1}{2} \|x\|_p^2$ , for  $1 over <math>\mathcal{X} = \mathcal{V} = \mathbb{R}^d$ . Let's remind the reader that the p-norm of a vector x is defined as  $(\sum_{i=1}^d |x_i|^p)^{\frac{1}{p}}$ . From Examples 4.17 and 6.21, we have that

 $\psi_{\mathcal{V}}^{\star}(\boldsymbol{\theta}) = \frac{1}{2} \|\boldsymbol{\theta}\|_q^2, \text{ where } \frac{1}{p} + \frac{1}{q} = 1, \text{ so that } q \geq 2. \text{ Let's calculate the dual maps: } (\nabla \psi(\boldsymbol{x}))_j = \operatorname{sign}(x_j) |x_j|^{p-1} \|\boldsymbol{x}\|_p^{2-p} \text{ and } (\nabla \psi_{\mathcal{V}}^{\star}(\boldsymbol{x}))_j = \operatorname{sign}(x_j) |x_j|^{q-1} \|\boldsymbol{x}\|_q^{2-q}. \text{ Hence, we can write the update rule as}$ 

$$\tilde{x}_{t+1,j} = \operatorname{sign}(x_{t,j}) |x_{t,j}|^{p-1} ||\boldsymbol{x}_t||_p^{2-p} - \eta g_{t,j}, \ j = 1, \dots, d,$$
  
$$x_{t+1,j} = \operatorname{sign}(\tilde{x}_{t+1,j}) |\tilde{x}_{t+1,j}|^{q-1} ||\tilde{\boldsymbol{x}}_{t+1}||_q^{2-q}, \ j = 1, \dots, d,$$

where we broke the update in two steps to simplify the notation (and the implementation). Starting from  $x_1 = 0$ , we have that

$$B_{\psi}(\boldsymbol{u};\boldsymbol{x}_1) = \psi(\boldsymbol{u}) - \psi(\boldsymbol{x}_1) - \langle \nabla \psi(\boldsymbol{x}_1), \boldsymbol{u} - \boldsymbol{x}_1 \rangle = \psi(\boldsymbol{u}).$$

The last ingredient is the fact that  $\psi(x)$  is p-1 strongly convex with respect to  $\|\cdot\|_p$ .

**Lemma 6.36** ([Shalev-Shwartz, 2007, Lemma 17]).  $\psi(x) = \frac{1}{2} ||x||_p^2$  is (p-1)-strongly convex with respect to  $||\cdot||_p$ , for  $1 \le p \le 2$ .

Hence, the regret bound will be

$$\sum_{t=1}^T (\ell_t(\boldsymbol{w}_t) - \ell_t(\boldsymbol{u})) \leq \frac{\|\boldsymbol{u}\|_p^2}{2\eta} + \frac{\eta}{2(p-1)} \sum_{t=1}^T \|\boldsymbol{g}_t\|_q^2 .$$

Setting p=2, we get the (unprojected) Online Subgradient Descent. However, we can set p to achieve a logarithmic dependency in the dimension d as in EG. Let's assume again that  $||g_t||_{\infty} \leq L_{\infty}$ , so we have

$$\sum_{t=1}^{T} \|\boldsymbol{g}_t\|_q^2 \le L_{\infty}^2 d^{2/q} T.$$

Also, note that  $\|u\|_p \leq \|u\|_1$ , so we have an upper bound to the regret of

$$\operatorname{Regret}_{T}(\boldsymbol{u}) \leq \frac{\|\boldsymbol{u}\|_{1}^{2}}{2n} + \frac{L_{\infty}^{2} d^{2/q} T \eta}{2(p-1)}, \ \forall \boldsymbol{u} \in \mathbb{R}^{d}.$$

Setting  $\eta = \frac{\alpha \sqrt{p-1}}{L_{\infty} d^{1/q} \sqrt{T}}$ , we get an upper bound to the regret of

$$\frac{1}{2}\left(\frac{\|\boldsymbol{u}\|_1^2}{\alpha} + \alpha\right)L_{\infty}\sqrt{T}\frac{d^{1/q}}{\sqrt{p-1}} = \frac{1}{2}\left(\frac{\|\boldsymbol{u}\|_1^2}{\alpha} + \alpha\right)L_{\infty}\sqrt{T}\sqrt{q-1}d^{1/q} \leq \frac{1}{2}\left(\frac{\|\boldsymbol{u}\|_1^2}{\alpha} + \alpha\right)L_{\infty}\sqrt{T}\sqrt{q}d^{1/q} \;.$$

Assuming  $d \geq 3$ , the choice of q that minimizes the last term is  $q = 2 \ln d$  that makes the term  $\sqrt{q} d^{1/q} = \sqrt{2e \ln d}$ . Hence, we have regret bound of the order of  $\mathcal{O}(\sqrt{T \ln d})$  as  $T \to \infty$ .

So, the *p*-norm allows to interpolate from the behaviour of OSD to the one of EG. Note that here the set  $\mathcal{V}$  is the entire space, however we could still set  $\mathcal{V} = \{ \boldsymbol{x} \in \mathbb{R}^d : x_i \geq 0, \|\boldsymbol{x}\|_1 = 1 \}$ . While this would allow us to get the same asymptotic bound of EG, the update would not be in a closed form anymore.

# 6.8 An Application of Online Mirror Descent: Learning with Expert Advice

Let's introduce a particular Online Convex Optimization game called Learning with Expert Advice.

In this setting, we have d experts that gives us some advice on each round. In turn, in each round we have to decide which expert we want to follow. After we made our choice, the losses associated to each expert are revealed and we pay the loss associated to the expert we picked. The aim of the game is to minimize the losses we make compared to cumulative losses of the best expert. This is a general setting that allows to model many interesting cases. For example, we have a number of different online learning algorithms and we would like to choose to the best among them.

Is this problem solvable? If we put ourselves in the adversarial setting, unfortunately it cannot be solved! Indeed, even with 2 experts, the adversary can force on us linear regret. Let's see how. In each round we have to pick expert 1 or expert 2. In each round, the adversary can decide that the expert we pick has loss 1 and the other one has loss 0. This means that the cumulative loss of the algorithm over T rounds is T. On the other hand, the best cumulative loss over expert 1 and 2 is less than T/2. This means that our regret, no matter what we do, can be as big as T/2.

The problem above is due to the fact that the adversary has too much power. One way to reduce its power is using randomization. We can allow the algorithm to be randomized and force the adversary to decide the losses at time t without knowing the outcome of the randomization of the algorithm at time t (but it can depend on the past randomization). This is enough to make the problem solvable. Moreover, it will also make the problem convex, allowing us to use any OCO algorithm on it.

First, let's write the problem in the original formulation. We set a discrete feasible set  $\mathcal{V} = \{e_i\}_{i=1}^d$ , where  $e_i$  is the vector will all zeros but a 1 in the coordinate i. Our predictions and the competitor are from  $\mathcal{V}$ . The losses are linear losses:  $\ell_t(x) = \langle g_t, x_t \rangle$ , for  $t = 1, \ldots, T$  and  $i = 1, \ldots, d$ . The regret is

$$\operatorname{Regret}_{T}(\boldsymbol{e}_{i}) = \sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} \rangle - \sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{e}_{i} \rangle, \ i = 1, \dots, d.$$
 (6.12)

The only thing that makes this problem non-convex is the feasibility set, that is clearly a non-convex one.

Let's now see how the randomization makes this problem convex. Let's extend the feasible set to  $V' = \{x \in \mathbb{R}^d : x_i \ge 0, ||x||_1 = 1\}$ . Note that  $e_i \in \mathcal{V}'$ . For this problem we can use an OCO algorithm to minimize the regret

$$\operatorname{Regret}_T'(\boldsymbol{u}) = \sum_{t=1}^T \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle - \sum_{t=1}^T \langle \boldsymbol{g}_t, \boldsymbol{u} \rangle, \ \forall \boldsymbol{u} \in \mathcal{V}' \ .$$

Can we find a way to transform an upper bound to this regret to the one we care in (6.12)? One way is the following one: On each time step, construct a random variable  $i_t$  that is equal to i with probability  $x_{t,i}$  for  $i = 1, \ldots, d$ . Then, select the expert according to the outcome of  $i_t$ . Now, in expectation we have

$$\mathbb{E}_{i_t}[g_{t,i_t}] = \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle,$$

and

$$\mathbb{E}[\mathrm{Regret}_T(\boldsymbol{e}_i)] = \mathbb{E}[\mathrm{Regret}_T'(\boldsymbol{e}_i)] = \mathbb{E}\left[\sum_{t=1}^T \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle - \sum_{t=1}^T \langle \boldsymbol{g}_t, \boldsymbol{e}_i \rangle\right] \ .$$

This means that we can minimize in expectation the non-convex regret with a randomized OCO algorithm. We can summarize this reasoning in Algorithm 6.3.

#### Algorithm 6.3 Learning with Expert Advice through Randomization

**Require:**  $x_1 \in \{x \in \mathbb{R}^d : x_i > 0, ||x||_1 = 1\}$ 

- 1: for t = 1 to T do
- 2: Draw  $i_t$  according to  $P(i_t = i) = x_{t,i}$
- 3: Select expert  $i_t$
- 4: Observe all the experts' losses  $g_t$  and pay the loss of the selected expert
- 5: Update  $x_t$  with an OCO algorithm with feasible set  $\{x \in \mathbb{R}^d : x_i > 0, \|x\|_1 = 1\}$
- 6: end for

For example, assume that  $\|g_t\|_{\infty} \le L_{\infty}$  for all t. Then, using the EG algorithm from Section 6.6, we obtain the following update rule

$$x_{t+1,j} = \frac{x_{t,j} \exp(-\eta g_{t,j})}{\sum_{i=1}^{d} x_{t,i} \exp(-\eta g_{t,i})}, \ j = 1, \dots, d,$$

where setting  $x_1=[1/d,\ldots,1/d]$  and  $\eta=\frac{\sqrt{2\ln d}}{L_\infty\sqrt{T}}$ . For such algorithm, the regret will be

$$\mathbb{E}[\operatorname{Regret}_T(\boldsymbol{e}_i)] \leq \frac{\sqrt{2}}{2} L_{\infty} \sqrt{T \ln d}, \ \forall \boldsymbol{e}_i \ .$$

It is worth stressing the importance of the result just obtained: We can design an algorithm that in expectation is close to the best expert in a set, *paying only a logarithmic penalty in the size of the set*. The *p*-norm Algorithm in Section 6.7 would give a similar guarantee.

In Section 10.6.1, we will see algorithms that achieve the better regret guarantee of  $\mathcal{O}(\sqrt{T \cdot \mathrm{KL}(\boldsymbol{u}; \boldsymbol{x}_1)})$  as  $T \to \infty$ , for any  $\boldsymbol{u}$  in the probability simplex. You should be able to convince yourself that no setting of  $\eta$  in EG allows to achieve such regret guarantee. Indeed, the algorithm will be based on a very different strategy.

### 6.9 Optimistic OMD

Till now, we have mainly considered the adversarial model as our model of the environment. This allowed us to design algorithm that work in this setting, as well as in other more benign settings. However, the world is never completely adversarial. So, we might be tempted to model the environment in some way, but that would leave our algorithm vulnerable to attacks. An alternative, is to consider the data as generated by some *predictable process plus an adversarial signal*. In this view, it might be beneficial to try to model the predictable part, without compromising the robustness to the adversarial signal.

In this section, we will explore this possibility through a particular version of OMD, where we *predict* the next gradient. In very intuitive terms, if our predicted gradient is correct, we can expect the regret to decrease. However, if our prediction is wrong we still want to recover the worst case guarantee. Such algorithm is called **Optimistic OMD**.

The core idea of Optimistic OMD is to predict the next gradient and use it in the update rule, as summarized in Algorithm 6.4. Here, at round t the algorithm receives a hint  $\tilde{g}_{t+1}$  on the next subgradient  $g_{t+1}$  and uses it to construct the update. At the same time, you have to remove the hint you used at the previous time step,  $\tilde{g}_t$ . Note that for the sake of the analysis, it does not matter how the prediction is generated. It can be even generated by another online learning procedure!

#### Algorithm 6.4 Optimistic Online Mirror Descent

```
Require: Non-empty closed convex \mathcal{V} \subset \mathcal{X} \subseteq \mathbb{R}^d, \psi: \mathcal{X} \to \mathbb{R} strictly convex and differentiable on \operatorname{int} \mathcal{X}, x_1 \in \operatorname{int} \mathcal{X}, \eta_1, \ldots, \eta_T > 0

1: \tilde{\boldsymbol{g}}_1 = \boldsymbol{0}

2: for t = 1 to T do

3: Output \boldsymbol{x}_t

4: Pay \ell_t(\boldsymbol{x}_t) for \ell_t: \mathcal{V} \to \mathbb{R} subdifferentiable in \mathcal{V}

5: Set \boldsymbol{g}_t \in \partial \ell_t(\boldsymbol{x}_t)

6: Predict next subgradient \tilde{\boldsymbol{g}}_{t+1} \in \mathbb{R}^d

7: \boldsymbol{x}_{t+1} \in \operatorname{argmin}_{\boldsymbol{x} \in \mathcal{V}} \langle \boldsymbol{g}_t - \tilde{\boldsymbol{g}}_t + \tilde{\boldsymbol{g}}_{t+1}, \boldsymbol{x} \rangle + \frac{1}{\eta_t} B_{\psi}(\boldsymbol{x}; \boldsymbol{x}_t)

8: end for
```

To gain some intuition on why this update makes sense, consider the case that  $\psi(\boldsymbol{x}) = \frac{1}{2} \|\boldsymbol{x}\|_2^2$ ,  $\eta_t = \eta$ , and  $\mathcal{V} = \mathbb{R}^d$ . In this case,  $\boldsymbol{x}_{t+1} = \boldsymbol{x}_t + \eta \tilde{\boldsymbol{g}}_t - \eta \boldsymbol{g}_t - \eta \tilde{\boldsymbol{g}}_{t+1}$ . Unrolling the update, we get  $\boldsymbol{x}_{t+1} = \boldsymbol{x}_1 - \eta (\tilde{\boldsymbol{g}}_{t+1} + \sum_{i=1}^t \boldsymbol{g}_i)$ . Without hints, that is in plain OMD, under the same assumptions the unrolled update would be  $\boldsymbol{x}_{t+1} = \boldsymbol{x}_1 - \eta \sum_{i=1}^t \boldsymbol{g}_i$  and  $\boldsymbol{x}_{t+2} = \boldsymbol{x}_1 - \eta \sum_{i=1}^{t+1} \boldsymbol{g}_i$ . Hence,  $\tilde{\boldsymbol{g}}_{t+1}$  acts as a proxy for the next (unknown) subgradient  $\boldsymbol{g}_t$ .

Note that one might be tempted to multiply  $\tilde{g}_t$  by  $\eta_{t-1}$ , because in the previous iteration we used the learning rate  $\eta_{t-1}$ . However, the OMD proof reveals that the correct way to see the update is to think the learning rate as attached to the Bregman divergence rather than to the subgradients.

One might also be tempted to find a way to study this algorithm with a special proof. However, the one-step lemma we proved for OMD is essentially tight: we only used two inequalities, one to deal with the set  $\mathcal{V}$  and the other one to linearize the losses. But, but steps can be made tight, considering  $\mathcal{V} = \mathbb{R}^d$  and linear losses. Hence, if the update is just OMD with a different sequence of subgradients, the proof *must* follow from the one of OMD with a different set of subgradients. This is a general rule: If we have a theorem based on a tight inequality, any other proof of the same theorem, no matter how complex, must be looser or in the best case equivalent.

Note that setting  $\tilde{g}_1 = 0$  is not a limitation because setting it to any other value would be equivalent to changing the arbitrary initial point  $x_1$ .

**Theorem 6.37.** Let  $B_{\psi}$  the Bregman divergence w.r.t.  $\psi : \mathcal{X} \to \mathbb{R}$  and assume  $\psi$  to be proper, closed, and  $\lambda$ -strongly convex with respect to  $\|\cdot\|$  in  $\mathcal{V}$ . Let  $\mathcal{V} \subseteq \mathcal{X}$  a non-empty closed convex set. With the notation in Algorithm 6.4, assume  $x_{t+1}$  exists, and it is in int  $\mathcal{X}$ .

Assume  $\eta_{t+1} \leq \eta_t$ , t = 1, ..., T. Then, and  $\forall u \in V$ , the following regret bounds hold

$$\sum_{t=1}^{T} (\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) \leq \max_{1 \leq t \leq T} \frac{B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_t)}{\eta_T} + \sum_{t=1}^{T} \left( \langle \boldsymbol{g}_t - \tilde{\boldsymbol{g}}_t, \boldsymbol{x}_t - \boldsymbol{x}_{t+1} \rangle - \frac{1}{\eta_t} B_{\psi}(\boldsymbol{x}_{t+1}; \boldsymbol{x}_t) \right)$$

$$\leq \max_{1 \leq t \leq T} \frac{B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_t)}{\eta_T} + \frac{1}{2\lambda} \sum_{t=1}^{T} \eta_t \|\boldsymbol{g}_t - \tilde{\boldsymbol{g}}_t\|_{\star}^2.$$

Moreover, if  $\eta_t$  is constant, i.e.,  $\eta_t = \eta \ \forall t = 1, \dots, T$ , we have

$$\begin{split} \sum_{t=1}^{T} (\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) &\leq \frac{B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_1)}{\eta} + \sum_{t=1}^{T} \left( \langle \boldsymbol{g}_t - \tilde{\boldsymbol{g}}_t, \boldsymbol{x}_t - \boldsymbol{x}_{t+1} \rangle - \frac{1}{\eta} B_{\psi}(\boldsymbol{x}_{t+1}; \boldsymbol{x}_t) \right) \\ &\leq \frac{B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_1)}{\eta} + \frac{\eta}{2\lambda} \sum_{t=1}^{T} \|\boldsymbol{g}_t - \tilde{\boldsymbol{g}}_t\|_{\star}^2 \,. \end{split}$$

*Proof.* We can use Lemma 6.10 with  $m{g}_t o m{g}_t - \tilde{m{g}}_t + \tilde{m{g}}_{t+1}$ , to have

$$\langle \boldsymbol{g}_t - \tilde{\boldsymbol{g}}_t + \tilde{\boldsymbol{g}}_{t+1}, \boldsymbol{x}_t - \boldsymbol{u} \rangle \leq \frac{1}{\eta_t} \left( B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_t) - B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_{t+1}) - B_{\psi}(\boldsymbol{x}_{t+1}; \boldsymbol{x}_t) \right) + \langle \boldsymbol{g}_t - \tilde{\boldsymbol{g}}_t + \tilde{\boldsymbol{g}}_{t+1}, \boldsymbol{x}_t - \boldsymbol{x}_{t+1} \rangle .$$

Summing over t = 1, ..., T the l.h.s., we obtain

$$egin{aligned} \sum_{t=1}^T \langle oldsymbol{g}_t - ilde{oldsymbol{g}}_t + ilde{oldsymbol{g}}_{t+1}, oldsymbol{x}_t - oldsymbol{u} 
angle &= \sum_{t=1}^T \langle oldsymbol{g}_t, oldsymbol{x}_t - oldsymbol{u} 
angle + \sum_{t=1}^T \langle oldsymbol{g}_{t+1} - ilde{oldsymbol{g}}_t, oldsymbol{x}_t - oldsymbol{u} 
angle \\ &= \sum_{t=1}^T \langle oldsymbol{g}_t, oldsymbol{x}_t - oldsymbol{u} 
angle + \langle ilde{oldsymbol{g}}_1 - ilde{oldsymbol{g}}_{T+1}, oldsymbol{u} 
angle + \sum_{t=1}^T \langle ilde{oldsymbol{g}}_{t+1} - ilde{oldsymbol{g}}_t, oldsymbol{x}_t 
angle \ . \end{aligned}$$

Summing the r.h.s., we have that

$$\sum_{t=1}^T \langle \boldsymbol{g}_t - \tilde{\boldsymbol{g}}_t + \tilde{\boldsymbol{g}}_{t+1}, \boldsymbol{x}_t - \boldsymbol{x}_{t+1} \rangle = \sum_{t=1}^T \langle \boldsymbol{g}_t - \tilde{\boldsymbol{g}}_t, \boldsymbol{x}_t - \boldsymbol{x}_{t+1} \rangle + \sum_{t=1}^T \langle \tilde{\boldsymbol{g}}_{t+1}, \boldsymbol{x}_t - \boldsymbol{x}_{t+1} \rangle \;.$$

Finally, observe that

$$\sum_{t=1}^T \langle \tilde{\boldsymbol{g}}_{t+1} - \tilde{\boldsymbol{g}}_t, \boldsymbol{x}_t \rangle - \sum_{t=1}^T \langle \tilde{\boldsymbol{g}}_{t+1}, \boldsymbol{x}_t - \boldsymbol{x}_{t+1} \rangle = \sum_{t=1}^T (\langle \tilde{\boldsymbol{g}}_{t+1}, \boldsymbol{x}_{t+1} \rangle - \langle \tilde{\boldsymbol{g}}_t, \boldsymbol{x}_t \rangle) = \langle \tilde{\boldsymbol{g}}_{T+1}, \boldsymbol{x}_{T+1} \rangle - \langle \tilde{\boldsymbol{g}}_1, \boldsymbol{x}_1 \rangle \; .$$

Given that the regret on the rounds t = 1, ..., T does not depend on  $\tilde{g}_{T+1}$ , we can safely set it to 0.

We defer the discussion of applications of optimistic algorithms to section on Optimistic FTRL in Section 7.12.

# **6.10** History Bits

The Bregman divergence was introduced by Bregman [1967] as a particular example of a distance-like function satisfying certain properties, to generalize the cyclic projection algorithm to general topological vector spaces. Often people drop the condition on the strict convexity [e.g., Bauschke et al., 2003] but in reality it is part of the original definition by Bregman [1967].

Mirror Descent (MD) was introduced by Nemirovskij and Yudin [1983] in the *offline* setting. The description of MD with Bregman divergence that I described here (with minor changes) was done by Beck and Teboulle [2003]. The minor changes are in decoupling the domain  $\mathcal{X}$  of  $\psi$  from the feasibility set  $\mathcal{V}$ . This allows to use functions  $\psi$  that do not satisfy the condition (6.5) but they satisfy (6.6). In the online setting, the mirror descent scheme was used for the first time by Warmuth and Jagota [1997].

Most of the online learning literature for OMD assumes  $\psi$  to be Legendre [see, e.g., Cesa-Bianchi and Lugosi, 2006] that corresponds to assuming (6.5) (or  $\lim_{x\to bdry} \chi \|\nabla\psi(x)\|_2 = +\infty$ , see [Rockafellar, 1970, Theorem 26.1 and Lemma 26.2]). This condition allows to prove that  $\nabla\psi^*_{\mathcal{V}} = (\nabla\psi_{\mathcal{V}})^{-1}$ . However, it turns out that the Legendre condition is not necessary and we only need the function  $\psi$  to be differentiable on the predictions  $x_t$ . For example, we only need one of the two conditions in (6.5) or (6.6) to hold. Removing the Legendre assumption makes it easier to use OMD with different combinations of feasibility sets/Bregman divergences. So, I did not introduce the concept of Legendre functions at all, relying instead on (a minor modification of) OMD as described by Beck and Teboulle [2003]. Theorem 6.8 is derived from [Bauschke and Borwein, 1997, Theorem 3.12].

The proof of Theorem 6.28 is based on the one in Kakade et al. [2009].

The local norms were introduced in Abernethy et al. [2008] for Follow-The-Regularized-Leader with self-concordant regularizers.

The EG algorithm was introduced by Kivinen and Warmuth [1997], but not as a specific instantiation of OMD. Beck and Teboulle [2003] rediscover EG for the offline case as an example of Mirror Descent. Later, Cesa-Bianchi and Lugosi [2006] show that EG is just an instantiation of OMD. The p-norm algorithms for online prediction were originally introduced by Grove et al. [1997, 2001]. The trick to set  $q=2\ln d$  is from Gentile and Littlestone [1999], Gentile [2003] (online learning) and apparently rediscovered in Ben-Tal et al. [2001] (optimization). The learning with experts setting was introduced by Littlestone and Warmuth [1994] and Vovk [1990]. The ideas in Algorithm 6.3 are based on the Multiplicative Weights algorithm [Littlestone and Warmuth, 1994] and the Hedge algorithm [Freund and Schapire, 1995, 1997]. As a side note, the weighted majority algorithm was also discovered independently in the game theory literature by Fudenberg and Levine [1995]. For two experts with losses in [0,1], Cover [1965] showed that the minimax regret is  $\sqrt{\frac{T}{2\pi}}$  and proposed an algorithm achieving it. Notably, the approach in Cover [1965] is based on online betting. On the other hand, for more than 2 experts and losses in [0,1], the minimax regret is  $(1+o(1))\sqrt{\frac{T \ln d}{2}}$ , where  $o(1) \to 0$  when  $d, T \to \infty$  [Cesa-Bianchi et al., 1993, 1997]. By now, the literature on learning with expert is huge, with tons of variations over algorithms and settings.

The idea of "hallucinating" future losses in online learning is originally from Azoury and Warmuth [2001] in the Forward Algorithm. Apparently, this idea was forgotten and rediscovered by Chiang et al. [2012] that used the previous loss function as an estimate of the next one, showing smaller regret in the case that the losses have small temporal variation. Later, Rakhlin and Sridharan [2013b] generalized this idea in the Optimistic OMD algorithm. Surprisingly enough, the procedure using two Optimistic OGD algorithms to solve saddle-point problems was already proposed by Popov [1980], see also Section 12.7. Optimistic OMD was proposed in Rakhlin and Sridharan [2013b] with a two-step update. It was then simplified to the one-step updates I presented here by Joulani et al. [2017]. However, Malitsky [2015] presented a version of Popov's algorithm for variational inequalities with only one projection that is essentially Optimistic OGD with one projection. The proof I present here is based on the one I proposed for Optimistic FTRL in Section 7.12.

### 6.11 Exercises

**Problem 6.1.** Historically, the negative entropy is associated with the use of the probability simplex as feasible set. However, it can also be applied to other feasible sets. So, derive a closed form update for OMD when using  $\psi$  of Example 6.6 and  $\mathcal{V} = \mathbb{R}^d \geq 0$ , that is the non-negative orthant.

**Problem 6.2.** Prove the three-points equality for Bregman divergences in Lemma 6.7.

**Problem 6.3.** Let  $A \in \mathbb{R}^{d \times d}$  a positive definite matrix. Define  $\|\mathbf{x}\|_{A}^{2} = \mathbf{x}^{\top} A \mathbf{x}$ . Prove that  $\frac{1}{2} \|\mathbf{x} - \mathbf{y}\|_{A}^{2}$  is the Bregman divergence  $B_{\psi}(\mathbf{x}; \mathbf{y})$  associated with  $\psi(\mathbf{x}) = \frac{1}{2} \|\mathbf{x}\|_{A}^{2}$ .

**Problem 6.4.** Let  $\psi : \mathcal{X} \to \mathbb{R}$  a valid distance generating function and  $D_{\psi}$  its associated Bregman divergence. Fix  $\mathbf{y} \in \operatorname{int} \mathcal{X}$  and define  $f(\mathbf{x}) = D_{\psi}(\mathbf{x}, \mathbf{y})$ . For any  $\mathbf{v} \in \operatorname{int} \mathcal{X}$  and  $\mathbf{x} \in \mathcal{X}$ , prove that  $D_f(\mathbf{x}; \mathbf{v}) = D_{\psi}(\mathbf{x}; \mathbf{v})$ .

**Problem 6.5.** We saw the Fenchel-Young inequality:  $\langle \theta, x \rangle \leq f(x) + f^*(\theta)$ . Now, we want to show an equality, quantifying the gap in the inequality with a Bregman divergence term. Assume that f and  $f^*$  are differentiable, f strictly convex, and dom  $f = \mathbb{R}^d$ . Prove that

$$f(\mathbf{x}) + f^{\star}(\mathbf{\theta}) = \langle \mathbf{\theta}, \mathbf{x} \rangle + B_f(\mathbf{x}; \nabla f^{\star}(\mathbf{\theta}))$$
.

**Problem 6.6.** Let  $f: \mathbb{R}^d \to (-\infty, +\infty]$  be even. Prove that  $f^*$  is even

**Problem 6.7.** In proof of Online Mirror Descent, we have the terms

$$-B_{\psi}(\boldsymbol{x}_{t+1};\boldsymbol{x}_t) + \langle \eta_t \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{x}_{t+1} \rangle$$
.

*Prove that they can be lower bounded by*  $B_{\psi}(\boldsymbol{x}_t; \boldsymbol{x}_{t+1})$ *.* 

**Problem 6.8.** Generalize the concept of strong convexity to Bregman functions, instead of norms, and prove a logarithmic regret guarantee for such functions using OMD.

**Problem 6.9.** Derive the EG update rule and regret bound in the case that the algorithm starts from an arbitrary vector  $\mathbf{x}_1$  in the probability simplex.

**Problem 6.10.** Show that EG is invariant to additive constants added to the loss vectors. Use this observation to show that the terms  $\sum_{i=1}^{d} g_{t,i}^2 x_{t,i}$  for  $t=1,\ldots,T$  in the regret upper bound can be tightened to  $\sum_{i=1}^{d} (g_{t,i}-m_t)^2 x_{t,i}$  for any  $m_t \in \mathbb{R}$ .

**Problem 6.11.** Extend Theorem 5.1 to arbitrary norms, measuring the diameter with respect to a norm  $\|\cdot\|$  and considering losses L-Lipschitz with respect to the dual norm  $\|\cdot\|_{\star}$ .

**Problem 6.12.** In this problem, we will tackle Online Non-Convex Optimization. Assume that  $\mathcal{V} \subset \mathbb{R}^d$  is the feasible set and it is convex and bounded. The losses  $\ell_t : \mathbb{R}^d \to [0,1]$  are non-convex and 1-Lipschitz w.r.t.  $\|\cdot\|_2$ . Prove that there exists a randomized algorithm that achieves sublinear regret on this problem, assuming knowledge of the total number of rounds T. Hint: Aim for something like  $\mathbb{E}[\operatorname{Regret}_T(\boldsymbol{u})] = \mathcal{O}(\sqrt{dT \ln T})$  and do not worry about efficiency of the algorithm.

# Chapter 7

# Follow-The-Regularized-Leader

Till now, we focused only on Online Subgradient Descent and its generalization, Online Mirror Descent, with a brief ad-hoc analysis of a Follow-The-Leader (FTL) analysis in the first chapter. In this chapter, we will extend FTL to a powerful and generic algorithm to do online convex optimization: Follow-the-Regularized-Leader (FTRL).

FTRL is a very intuitive algorithm: At each time step it will play the minimizer of the sum of the past losses plus a time-varying regularization. We will see that the regularization is needed to make the algorithm "more stable" with linear losses and avoid the jumping back and forth that we saw in Example 2.10.

#### 7.1 The Follow-the-Regularized-Leader Algorithm

Algorithm 7.1 Follow-the-Regularized-Leader Algorithm

**Require:** A sequence of regularizers  $\psi_1, \dots, \psi_T : \mathcal{X} \to \mathbb{R}$ , closed non-empty set  $\mathcal{V} \subseteq \mathcal{X} \subseteq \mathbb{R}^d$ 

- 1: for t = 1 to T do
- Output  $x_t \in \operatorname{argmin}_{x \in \mathcal{V}} \ \psi_t(x) + \sum_{i=1}^{t-1} \ell_i(x)$ Receive  $\ell_t : \mathcal{V} \to \mathbb{R}$  and pay  $\ell_t(x_t)$
- 4: end for

As said above, in FTRL we output the minimizer of the regularized cumulative past losses. It should be clear that FTRL is not an algorithm, but rather a family of algorithms, in the same way as OMD is a family of algorithms.

Before analyzing the algorithm, let's get some intuition on it. In OMD, we saw that the "state" of the algorithm is stored in the current iterate  $x_t$ , in the sense that the next iterate  $x_{t+1}$  depends on  $x_t$  and the loss received at time t, plus obviously the choice of the learning rate. Instead in FTRL, the next iterate  $x_{t+1}$  depends on the entire history of losses received up to time t and on the regularizer used at time t. This has an immediate consequence: In the case that  $\mathcal{V}$  is bounded, OMD will only "remember" the last  $x_t$  and nothing else. On the other hand, FTRL keeps in memory the entire history of the past, that in principle allows to recover the iterates before the projection in  $\mathcal{V}$ .

This difference in behavior might make the reader think that FTRL is more computationally and memory expensive. And indeed it is! But, we will also see that there is a way to consider approximate losses that makes the algorithm as expensive as OMD, yet retaining the same or more information than OMD.

For FTRL, we prove an equality for the regret. This equality factors the regret in three terms that have precise meanings and can be easily upper bounded with some familiar quantities.

**Lemma 7.1.** Let  $\psi_1, \ldots, \psi_T : \mathcal{X} \to \mathbb{R}$  be a sequence of regularization functions and  $\mathcal{V} \subseteq \mathcal{X} \subseteq \mathbb{R}^d$  a closed and non-empty set. Denote by  $F_t(\mathbf{x}) = \psi_t(\mathbf{x}) + \sum_{i=1}^{t-1} \ell_i(\mathbf{x})$ . Assume that  $\operatorname{argmin}_{\mathbf{x} \in \mathcal{V}} F_t(\mathbf{x})$  is not empty and set  $\mathbf{x}_t \in \operatorname{argmin}_{\mathbf{x} \in \mathcal{V}} F_t(\mathbf{x})$ . Then, for any  $\mathbf{u} \in \mathbb{R}^d$ , we have

$$\sum_{t=1}^{T} (\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) = \psi_{T+1}(\boldsymbol{u}) - \min_{\boldsymbol{x} \in \mathcal{V}} \psi_1(\boldsymbol{x}) + \sum_{t=1}^{T} [F_t(\boldsymbol{x}_t) - F_{t+1}(\boldsymbol{x}_{t+1}) + \ell_t(\boldsymbol{x}_t)] + F_{T+1}(\boldsymbol{x}_{T+1}) - F_{T+1}(\boldsymbol{u}).$$

*Proof.* Given that the terms  $\ell_t(x_t)$  are appearing at both side of the equality, we just have to verify that

$$-\sum_{t=1}^{T} \ell_t(\boldsymbol{u}) = \psi_{T+1}(\boldsymbol{u}) - \min_{\boldsymbol{x} \in \mathcal{V}} \psi_1(\boldsymbol{x}) + \sum_{t=1}^{T} [F_t(\boldsymbol{x}_t) - F_{t+1}(\boldsymbol{x}_{t+1})] + F_{T+1}(\boldsymbol{x}_{T+1}) - F_{T+1}(\boldsymbol{u}).$$

Remembering that  $F_1(x_1) = \min_{x \in \mathcal{V}} \psi_1(x)$  and using the fact that the sum with  $F_t$  is telescopic, we have

$$-\sum_{t=1}^{T} \ell_t(\boldsymbol{u}) = \psi_{T+1}(\boldsymbol{u}) - F_1(\boldsymbol{x}_1) + F_1(\boldsymbol{x}_1) - F_{T+1}(\boldsymbol{x}_{T+1}) + F_{T+1}(\boldsymbol{x}_{T+1}) - F_{T+1}(\boldsymbol{u}) = \psi_{T+1}(\boldsymbol{u}) - F_{T+1}(\boldsymbol{u}),$$

that is true by the definition of  $F_{T+1}$ .

**Remark 7.2.** We basically did not assume anything on  $\ell_t$  nor on  $\psi_t$ , hence the above equality holds even for non-convex losses and regularizers. Yet, solving the minimization problem at each step might be computationally infeasible.

**Remark 7.3.** Note that the left hand side of the equality in the theorem does not depend on  $\psi_{T+1}$ . So, we will often set  $\psi_{T+1}$  equal to  $\psi_T$ .

Remark 7.4. The FTRL algorithm is invariant to any constant added to the regularizers, hence we can always state the regret guarantee with  $\psi_t(\mathbf{u}) - \min_{\mathbf{x}} \psi_t(\mathbf{x})$  instead of  $\psi_t(\mathbf{u})$ . However, for clarity, we will sometimes explicitly choose the regularizers such that their minimum is 0.

**Remark 7.5.** The terms  $\ell_t(\mathbf{x}_t)$  appear on the left and right of the equality. Hence, in some proofs we can substitute them with some other terms, for example  $\ell_t(\tilde{\mathbf{x}}_t)$  where  $\tilde{\mathbf{x}}_t$  is not the FTRL prediction. In other words, we can write the same equality for the prediction of a generic algorithm whose regret will depend on the prediction of the FTRL algorithm.

However, while surprising, the above equality is not yet a regret bound, because it is "implicit". In fact, the losses are appearing on both sides of the equality.

Let's take a closer look at the equality. If  $u \in \mathcal{V}$ , we have that the sum of the last two terms on the r.h.s. is negative. On the other hand, the first two terms on the r.h.s. are similar to what we got in OMD. The interesting part is the sum of the terms  $F_t(x_t) - F_{t+1}(x_{t+1}) + \ell_t(x_t)$ . To give an intuition of what is going on, let's consider that case that the regularizer is constant over time, i.e.,  $\psi_t = \psi$ . Hence, the terms in the sum can be rewritten as

$$F_t(\boldsymbol{x}_t) - F_{t+1}(\boldsymbol{x}_{t+1}) + \ell_t(\boldsymbol{x}_t) = \psi(\boldsymbol{x}_t) + \sum_{i=1}^t \ell_i(\boldsymbol{x}_t) - \left(\psi(\boldsymbol{x}_{t+1}) + \sum_{i=1}^t \ell_i(\boldsymbol{x}_{t+1})\right).$$

Hence, we are measuring the distance between the value of the regularized losses in two consecutive predictions of the algorithms. Roughly speaking, if  $x_t \approx x_{t+1}$  and the losses+regularization are "nice" then this term will be small. This should remind you exactly the OMD update, where we *constrain*  $x_{t+1}$  to be close to  $x_t$ . Instead, here the two predictions will be close one to the other if the minimizer of the regularized losses up to time t is close to the minimizer of the losses up to time t + 1. So, like in OMD, the regularizer here will play the critical role of *stabilizing* the predictions, if the losses do not possess enough curvature.

In the following, we will see different ways to get an explicit upper bound from Lemma 7.1.

# 7.2 FTRL Regret Bound using Strong Convexity

An easy case to get a regret upper bound for FTRL is when the losses plus the regularizer are strongly convex. In fact, the strong convexity guarantees the predictions to be stable as we prove in the next lemmas.

#### 7.2.1 An Explicit Regret Bound

We now state a Lemma quantifying the intuition on the "stability" of the predictions.

**Lemma 7.6.** With the notation in Algorithm 7.1, denote by  $F_t(x) = \psi_t(x) + \sum_{i=1}^{t-1} \ell_i(x)$ . Assume  $\mathcal{V} \subseteq \mathcal{X}$  and  $\mathcal{V}$  convex. If  $F_t$  is closed, subdifferentiable, and strongly convex in  $\mathcal{V}$ , then  $x_t$  exists and is unique. In addition, assume  $\partial \ell_t(x_t)$  to be non-empty and  $F_t + \ell_t$  to be closed, subdifferentiable, and  $\lambda_t$ -strongly convex w.r.t.  $\|\cdot\|$  in  $\mathcal{V}$ . Then, we have

$$F_{t}(\boldsymbol{x}_{t}) - F_{t+1}(\boldsymbol{x}_{t+1}) + \ell_{t}(\boldsymbol{x}_{t}) \leq \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{x}_{t+1} \rangle - \frac{\lambda}{2} \|\boldsymbol{x}_{t} - \boldsymbol{x}_{t+1}\|^{2} + \psi_{t}(\boldsymbol{x}_{t+1}) - \psi_{t+1}(\boldsymbol{x}_{t+1})$$

$$\leq \frac{\|\boldsymbol{g}_{t}\|_{\star}^{2}}{2\lambda_{t}} + \psi_{t}(\boldsymbol{x}_{t+1}) - \psi_{t+1}(\boldsymbol{x}_{t+1}), \ \forall \boldsymbol{g}_{t} \in \partial \ell_{t}(\boldsymbol{x}_{t}).$$

Proof. The existence and unicity is given by Theorem 6.9. Then, we have

$$F_{t}(\boldsymbol{x}_{t}) - F_{t+1}(\boldsymbol{x}_{t+1}) + \ell_{t}(\boldsymbol{x}_{t}) = (F_{t}(\boldsymbol{x}_{t}) + \ell_{t}(\boldsymbol{x}_{t})) - (F_{t}(\boldsymbol{x}_{t+1}) + \ell_{t}(\boldsymbol{x}_{t+1})) + \psi_{t}(\boldsymbol{x}_{t+1}) - \psi_{t+1}(\boldsymbol{x}_{t+1})$$

$$\leq \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{x}_{t+1} \rangle - \frac{\lambda}{2} \|\boldsymbol{x}_{t} - \boldsymbol{x}_{t+1}\|^{2} + \psi_{t}(\boldsymbol{x}_{t+1}) - \psi_{t+1}(\boldsymbol{x}_{t+1}),$$

where in the second inequality we used Lemma 4.2 for the function  $F_t + \ell_t + i_{\mathcal{V}}$  with  $\mathbf{g}_t \in \partial (F_t + \ell_t + i_{\mathcal{V}})(\mathbf{x}_t)$ . Observing that  $\mathbf{x}_t = \operatorname{argmin}_{\mathbf{x} \in \mathcal{V}} F_t(\mathbf{x})$ , we have  $\mathbf{0} \in \partial (F_t + i_{\mathcal{V}})(\mathbf{x}_t)$  by Theorem 6.29. Hence, using Theorem 2.22, we have  $\partial \ell_t(\mathbf{x}_t) \subseteq \partial (F_t + \ell_t + i_{\mathcal{V}})(\mathbf{x}_t)$ .

The second inequality is obtained observing that  $\langle \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{x}_{t+1} \rangle \leq \|\boldsymbol{g}_t\|_\star \|\boldsymbol{x}_t - \boldsymbol{x}_{t+1}\|$  and using the elementary inequality  $ax - \frac{b}{2}x^2 \leq \frac{a^2}{2b}$  for  $x \in \mathbb{R}$  and a, b > 0.

Let's see some immediate applications of this lemma.

**Corollary 7.7.** With the notation in Algorithm 7.1, let  $\mathcal{V}$  be convex and let  $\psi: \mathcal{V} \to \mathbb{R}$  be a closed and  $\mu$ -strongly convex function w.r.t.  $\|\cdot\|$ . Set the sequence of regularizers as  $\psi_t(\boldsymbol{x}) = \frac{1}{\eta_{t-1}}(\psi(\boldsymbol{x}) - \min_{\boldsymbol{z}} \psi(\boldsymbol{z}))$ , where  $\eta_{t+1} \leq \eta_t$ ,  $t = 1, \ldots, T$ . Assume  $\ell_t$  convex, closed, and  $\partial \ell_t(\boldsymbol{x}_t)$  not empty. Then, FTRL guarantees

$$\sum_{t=1}^{T} \ell(\boldsymbol{x}_{t}) - \sum_{t=1}^{T} \ell_{t}(\boldsymbol{u}) \leq \frac{\psi(\boldsymbol{u}) - \min_{\boldsymbol{x} \in \mathcal{V}} \psi(\boldsymbol{x})}{\eta_{T-1}} + \frac{1}{2\mu} \sum_{t=1}^{T} \eta_{t-1} \|\boldsymbol{g}_{t}\|_{\star}^{2},$$

for all  $g_t \in \partial \ell_t(x_t)$ . Moreover, if the functions  $\ell_t$  are L-Lipschitz, setting  $\eta_{t-1} = \frac{\alpha \sqrt{\mu}}{L\sqrt{t}}$  we get

$$\sum_{t=1}^{T} \ell(\boldsymbol{x}_t) - \sum_{t=1}^{T} \ell_t(\boldsymbol{u}) \le \left(\frac{\psi(\boldsymbol{u}) - \min_{\boldsymbol{x}} \psi(\boldsymbol{x})}{\alpha} + \alpha\right) \frac{L\sqrt{T}}{\sqrt{\mu}}.$$

*Proof.* The corollary is immediate from Lemma 7.1, Lemma 7.6, and the observation that from the assumptions we have  $\psi_t(\boldsymbol{x}) - \psi_{t+1}(\boldsymbol{x}) \leq 0$ ,  $\forall \boldsymbol{x}$ . We also set  $\psi_{T+1} = \psi_T$ , thanks to Remark 7.3.

This might look like the same regret guarantee of OMD, however here there is a very important difference: The last term contains a time-varying element  $(\eta_t)$  but the domain does not have to be bounded! Also, I used the regularizer  $\frac{1}{\eta_{t-1}}\psi(x)$  and not  $\frac{1}{\eta_t}\psi(x)$  to remind you another important difference: In OMD the learning rate  $\eta_t$  is chosen after receiving information about  $\ell_t$ , through the subgradient  $g_t$ , while here you have to choose it *before* observing  $\ell_t$ .

#### 7.2.2 Proximal Regularizers

We can obtain a slightly stronger guarantee in the case that the regularizer is *proximal*, that is it satisfies that  $x_t \in \operatorname{argmin}_{x \in \mathcal{V}} \psi_{t+1}(x) - \psi_t(x)$ .

**Lemma 7.8.** With the notation in Algorithm 7.1, denote by  $F_t(\mathbf{x}) = \psi_t(\mathbf{x}) + \sum_{i=1}^{t-1} \ell_i(\mathbf{x})$  for all t. Assume  $\mathcal{V} \subseteq \mathcal{X}$  and  $\mathcal{V}$  convex. Also, assume that  $F_{t+1}$  is closed, subdifferentiable, and  $\lambda_{t+1}$ -strongly convex w.r.t.  $\|\cdot\|$  in  $\mathcal{V}$ , the regularizer is such that  $\mathbf{x}_t \in \operatorname{argmin}_{\mathbf{x} \in \mathcal{V}} \psi_{t+1}(\mathbf{x}) - \psi_t(\mathbf{x})$ . Then,  $\mathbf{x}_{t+1}$  exists and is unique. Moreover, if  $\partial \ell_t(\mathbf{x}_t)$  is non-empty, we have

$$F_{t}(\boldsymbol{x}_{t}) - F_{t+1}(\boldsymbol{x}_{t+1}) + \ell_{t}(\boldsymbol{x}_{t}) \leq \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{x}_{t+1} \rangle - \frac{\lambda}{2} \|\boldsymbol{x}_{t} - \boldsymbol{x}_{t+1}\|^{2} + \psi_{t}(\boldsymbol{x}_{t}) - \psi_{t+1}(\boldsymbol{x}_{t})$$

$$\leq \frac{\|\boldsymbol{g}_{t}\|_{\star}^{2}}{2\lambda_{t+1}} + \psi_{t}(\boldsymbol{x}_{t}) - \psi_{t+1}(\boldsymbol{x}_{t}), \ \forall \boldsymbol{g}_{t} \in \partial \ell_{t}(\boldsymbol{x}_{t}).$$

*Proof.* The existence and unicity is given by Theorem 6.9. We have

$$F_{t}(\boldsymbol{x}_{t}) - F_{t+1}(\boldsymbol{x}_{t+1}) + \ell_{t}(\boldsymbol{x}_{t}) = (F_{t}(\boldsymbol{x}_{t}) + \ell_{t}(\boldsymbol{x}_{t}) + \psi_{t+1}(\boldsymbol{x}_{t}) - \psi_{t}(\boldsymbol{x}_{t})) - F_{t+1}(\boldsymbol{x}_{t+1}) - \psi_{t+1}(\boldsymbol{x}_{t}) + \psi_{t}(\boldsymbol{x}_{t})$$

$$= F_{t+1}(\boldsymbol{x}_{t}) - F_{t+1}(\boldsymbol{x}_{t+1}) - \psi_{t+1}(\boldsymbol{x}_{t}) + \psi_{t}(\boldsymbol{x}_{t})$$

$$\leq \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{x}_{t+1} \rangle - \frac{\lambda}{2} \|\boldsymbol{x}_{t} - \boldsymbol{x}_{t+1}\|^{2} - \psi_{t+1}(\boldsymbol{x}_{t}) + \psi_{t}(\boldsymbol{x}_{t}),$$

where in the second inequality we used Lemma 4.2 for the function  $F_{t+1}+i_{\mathcal{V}}$  with  $\boldsymbol{g}_t\in\partial(F_{t+1}+i_{\mathcal{V}})(\boldsymbol{x}_t)$ . Observing that, from the proximal property, we have that  $\boldsymbol{x}_t=\operatorname{argmin}_{\boldsymbol{x}\in\mathcal{V}} F_t(\boldsymbol{x})+\psi_{t+1}(\boldsymbol{x})-\psi_t(\boldsymbol{x})$ , from Theorem 6.29 we have  $\boldsymbol{0}\in\partial(F_t+i_{\mathcal{V}}+\psi_{t+1}-\psi_t)(\boldsymbol{x}_t)$ . Hence, using Theorem 2.22, and remembering that  $F_{t+1}(\boldsymbol{x})=F_t(\boldsymbol{x})+\ell_t(\boldsymbol{x})+\psi_{t+1}(\boldsymbol{x})-\psi_t(\boldsymbol{x})$ , we have that  $\partial\ell_t(\boldsymbol{x}_t)\subseteq\partial(F_{t+1}+i_{\mathcal{V}})(\boldsymbol{x}_t)$ .

The second inequality is obtained observing that  $\langle \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{x}_{t+1} \rangle \leq \|\boldsymbol{g}_t\|_{\star} \|\boldsymbol{x}_t - \boldsymbol{x}_{t+1}\|$  and using the elementary inequality  $ax - \frac{b}{2}x^2 \leq \frac{a^2}{2b}$  for  $x \in \mathbb{R}$  and a, b > 0.

**Remark 7.9.** Note that a constant regularizer is proximal because any point is the minimizer of the zero function. On the other hand, a constant regularizer makes Lemmas 7.6 and 7.8 the same.

**Example 7.10.** An example of proximal regularization is  $\psi_t(\mathbf{x}) = \frac{1}{2} \sum_{i=1}^{t-1} \|\mathbf{x}_t - \mathbf{x}\|_2^2$ . It is easy to see that this is t-1 strongly convex with respect to the  $L_2$  norm. Using this regularizer with linear losses gives an algorithm known as FTRL-Proximal. This algorithm lies in between FTRL and OMD, indeed it solves the issue of being "one-step-behind" compared to OMD explained in the previous section, but now its regret depend on  $\frac{1}{2} \sum_{i=1}^{T} \|\mathbf{x}_t - \mathbf{u}\|_2^2$  that is not easily controlled, unless V has a bounded diameter. However, the main advantage of FTRL-Proximal is the possibility to deal with non-smooth regularizers (see 7.8), that it is not possible in OMD.

### 7.3 FTRL with Linearized Losses

An important difference between OMD and FTRL is that here the update rule seems way more expensive than in OMD, because we need to solve an optimization problem at each step. However, it turns out we can use FTRL on *linearized losses* and obtain the same bound with the same computational complexity of OMD.

Consider the case in which the losses are linear, i.e.,  $\ell_t(x) = \langle g_t, x \rangle$ ,  $t = 1, \dots, T$ , we have that the prediction of FTRL is

$$x_{t+1} \in \underset{x \in \mathcal{V}}{\operatorname{argmin}} \ \psi_{t+1}(x) + \sum_{i=1}^{t} \langle g_i, x \rangle = \underset{x \in \mathcal{V}}{\operatorname{argmax}} \left\langle -\sum_{i=1}^{t} g_i, x \right\rangle - \psi_{t+1}(x) \ .$$

Denote by  $\psi_{\mathcal{V},t}(\boldsymbol{x}) = \psi_t(\boldsymbol{x}) + i_{\mathcal{V}}(\boldsymbol{x})$ . Now, if we assume  $\psi_{\mathcal{V},t}$  to be proper, convex, and closed, using the Theorem 6.16, we have that  $\boldsymbol{x}_{t+1} \in \partial \psi_{\mathcal{V},t+1}^{\star}(-\sum_{i=1}^{t}\boldsymbol{g}_i)$ . Moreover, if  $\psi_{\mathcal{V},t+1}$  is also strongly convex, by Theorem 6.28 we know that  $\psi_{\mathcal{V},t+1}^{\star}$  is differentiable and we get

$$\boldsymbol{x}_{t+1} = \nabla \psi_{\mathcal{V},t+1}^{\star} \left( -\sum_{i=1}^{t} \boldsymbol{g}_{i} \right) . \tag{7.1}$$

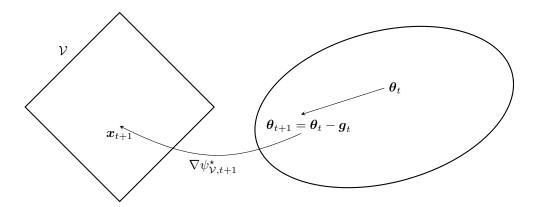

Figure 7.1: Dual mapping for FTRL with linear losses.

In turn, this update can be written in the following way

$$egin{aligned} oldsymbol{ heta}_{t+1} &= oldsymbol{ heta}_t - oldsymbol{g}_t, \ oldsymbol{x}_{t+1} &= 
abla \psi_{\mathcal{V},t+1}^{\star}(oldsymbol{ heta}_{t+1}) \; . \end{aligned}$$

This corresponds to Figure 7.1.

Compare it to the mirror update of OMD, rewritten in a similar way:

$$\theta_{t+1} = \nabla \psi(\boldsymbol{x}_t) - \eta_t \boldsymbol{g}_t, \boldsymbol{x}_{t+1} = \nabla \psi_{\mathcal{V}}^{\star}(\boldsymbol{\theta}_{t+1}).$$

They are very similar, but with important differences:

- In OMD, the state is kept in  $x_t$ , so we need to transform it into a dual variable before making the update and then back to the primal variable.
- In FTRL with linear losses, the state is kept directly in the dual space, updated and then transformed in the primal variable. The primal variable is only used to predict, but not directly in the update.
- In OMD, the samples are weighted by the learning rates that is typically decreasing
- In FTRL with linear losses, all the subgradients have the same weight, but the regularizer is typically increasing over time.

Also, we will not lose anything in the worst-case regret bound! Indeed, we can run FTRL on the linearized losses  $\tilde{\ell}_t(x) = \langle g_t, x \rangle$ , where  $g_t \in \partial \ell_t(x_t)$ , guaranteeing exactly the same worst-case upper bound on the regret with the losses  $\ell_t$ . The algorithm for such procedure is in Algorithm 7.2.

### Algorithm 7.2 Follow-the-Regularized-Leader Algorithm on Linearized Losses

**Require:** A sequence of regularizers  $\psi_1, \dots, \psi_T : \mathcal{X} \to \mathbb{R}$ , closed non-empty convex set  $\mathcal{V} \subseteq \mathcal{X} \subseteq \mathbb{R}^d$ 

- 1: for t = 1 to T do
- 2: Output  $x_t \in \operatorname{argmin}_{x \in \mathcal{V}} \ \psi_t(x) + \sum_{i=1}^{t-1} \langle g_i, x \rangle$
- 3: Pay  $\ell_t(x_t)$  for  $\ell_t: \mathcal{V} \to \mathbb{R}$  subdifferentiable in  $\mathcal{V}$
- 4: Set  $\boldsymbol{g}_t \in \partial \ell_t(\boldsymbol{x}_t)$
- 5: end for

In fact, using the definition of the subgradients and the assumptions of Corollary 7.7, we have

$$\operatorname{Regret}_T(\boldsymbol{u}) = \sum_{t=1}^T (\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) \leq \sum_{t=1}^T (\tilde{\ell}_t(\boldsymbol{x}_t) - \tilde{\ell}_t(\boldsymbol{u})) \leq \frac{\psi(\boldsymbol{u}) - \min_{\boldsymbol{x} \in \mathcal{V}} \psi(\boldsymbol{x})}{\eta_{T-1}} + \frac{1}{2\mu} \sum_{t=1}^T \eta_{t-1} \|\boldsymbol{g}_t\|_{\star}^2, \ \forall \boldsymbol{u} \in \mathcal{V}.$$

The only difference with respect to Corollary 7.7 is that here the  $g_t$  are the specific ones we use in the algorithm, while in Corollary 7.7 the statement holds for any choice of the  $g_t \in \partial \ell_t(x_t)$ . Moreover, FTRL with exact losses can adapt to any "nice" properties of the losses, for example strong convexity, while this information is lost in the linearized case. We also have to remember that this is just a worst-case guarantee: On real problems FTRL with full losses typically performs better than both FTRL with linearized losses and OMD.

More generally, we can also specialize the FTRL regret equality to this case, obtaining the following Lemma, that is usually considered a "dual analysis" of FTRL for linear losses.

**Lemma 7.11.** Under the assumptions of Lemma 7.1, further assume for all t that  $\ell_t(x) = \langle g_t, x \rangle$ . Then, for any  $u \in \mathbb{R}^d$ , we have

$$\sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{u} \rangle = \psi_{\mathcal{V}, T+1}(\boldsymbol{u}) + \psi_{\mathcal{V}, 1}^{\star}(\boldsymbol{0}) + \sum_{t=1}^{T} \left[ \psi_{\mathcal{V}, t+1}^{\star} \left( -\sum_{i=1}^{t} \boldsymbol{g}_{i} \right) - \psi_{\mathcal{V}, t}^{\star} \left( -\sum_{i=1}^{t-1} \boldsymbol{g}_{i} \right) + \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} \rangle \right]$$
$$- \psi_{\mathcal{V}, T+1}^{\star} \left( -\sum_{i=1}^{T} \boldsymbol{g}_{i} \right) - \psi_{\mathcal{V}, T+1}(\boldsymbol{u}) - \left\langle \sum_{i=1}^{T} \boldsymbol{g}_{i}, \boldsymbol{u} \right\rangle,$$

where  $\psi_{\mathcal{V},t}^{\star}$  is the Fenchel conjugate of  $\psi_{\mathcal{V},t} = \psi_t + i_{\mathcal{V}}$ . Also, by Fenchel-Young inequality, the sum of the last three terms is non-positive.

*Proof.* The proof is immediate by just summing up the terms on both sides.

We can also obtain it from Lemma 7.1, observing that

$$F_t(\boldsymbol{x}_t) = \min_{\boldsymbol{x} \in \mathcal{V}} \ \psi_t(\boldsymbol{x}) + \sum_{i=1}^{t-1} \ell_i(\boldsymbol{x}) = -\max_{\boldsymbol{x} \in \mathcal{V}} \left\langle -\sum_{i=1}^{t-1} \boldsymbol{g}_i, \boldsymbol{x} \right\rangle - \psi_t(\boldsymbol{x}) = -\psi_{\mathcal{V}, t}^{\star} \left( -\sum_{i=1}^{t-1} \boldsymbol{g}_i \right),$$

and using the fact that  $\psi_{\mathcal{V},1}^{\star}(\mathbf{0}) = -\inf_{\boldsymbol{x} \in \mathbb{R}^d} \psi_{\mathcal{V},1}(\boldsymbol{x})$ .

Remark 7.12. While the regularizer  $\psi_t$  in FTRL plays the same role of the distance generating function in OMD, it is important to note that  $\psi$  must be differentiable in OMD. Indeed, it is necessary for the existence of the Bregman divergence, and for the uniqueness of the dual map  $\nabla \psi$ . Instead, in FTRL the dual map  $\nabla \psi$  is not used, as it can be seen in Figure 7.1. We will use this property of FTRL in Section 7.8, when we will use regularizers that contains a non-differentiable component. However, we can express the above bound using the notion of generalized Bregman divergence  $\bar{B}_{\psi}: \mathbb{R}^d \times \mathbb{R}^d \to \mathbb{R}_{\geq 0}$  defined as  $\bar{B}_{\psi}(x; \theta) = \psi(x) + \psi^*(\theta) - \langle \theta, x \rangle$ . By the Fenchel-Young inequality,  $\bar{B}_{\psi}(x; \theta) \geq 0$ . Observe that we do not require  $\psi$  to be differentiable. However, if  $\psi$  is differentiable, then from Theorem 6.16 we have  $B_{\psi}(x; y) = \bar{B}_{\psi}(x; \nabla \psi(y))$ . With this definition and assuming that  $\inf_{x \in \mathcal{V}} \psi_1(x) = \inf_{x \in \mathcal{V}} \psi_{T+1}(x)$ , the previous upper bound is

$$\sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{u} \rangle = \bar{B}_{\psi_{\mathcal{V},T+1}}(\boldsymbol{u}; \boldsymbol{0}) + \sum_{t=1}^{T} \left[ \bar{B}_{\psi_{\mathcal{V},t+1}}(\boldsymbol{u}; \boldsymbol{\theta}_{t+1}) - \bar{B}_{\psi_{\mathcal{V},t}}(\boldsymbol{u}; \boldsymbol{\theta}_{t}) + \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} \rangle \right] - \bar{B}_{\psi_{\mathcal{V},T+1}}(\boldsymbol{u}; \boldsymbol{\theta}_{T+1}),$$

where  $\boldsymbol{\theta}_t = -\sum_{i=1}^{t-1} \boldsymbol{g}_i$ .

In the next example, we can see the different behavior of FTRL and OMD.

**Example 7.13.** Consider  $V = \{x \in \mathbb{R}^d : ||x||_2 \le 1\}$ . With Online Subgradient Descent (OSD) with learning rate  $\eta_t = \frac{1}{\sqrt{t}}$  and  $x_1 = 0$ , the update is

$$egin{aligned} & ilde{oldsymbol{x}}_{t+1} = oldsymbol{x}_t - rac{1}{\sqrt{t}} oldsymbol{g}_t, \ & oldsymbol{x}_{t+1} = ilde{oldsymbol{x}}_{t+1} \min \left( rac{1}{\| ilde{oldsymbol{x}}_{t+1}\|_2}, 1 
ight) \,. \end{aligned}$$

On the other hand in FTRL with linearized losses, we can use  $\psi_t(\mathbf{x}) = \frac{\sqrt{t}}{2} ||\mathbf{x}||_2^2$  and it is easy to verify that the update in (7.1) becomes

$$egin{aligned} & ilde{oldsymbol{x}}_{t+1} = rac{-\sum_{i=1}^t oldsymbol{g}_i}{\sqrt{t}}, \ & oldsymbol{x}_{t+1} = ilde{oldsymbol{x}}_{t+1} \min\left(rac{1}{\| ilde{oldsymbol{x}}_{t+1}\|_2}, 1
ight) \,. \end{aligned}$$

While the regret guarantee would be the same for these two updates, from an intuitive point of view OMD seems to be losing a lot of potential information due to the fact that we only memorize the projected iterate.

#### 7.3.1 FTRL with Linearized Losses Can Be Equivalent to OMD

Even if FTRL and OMD seem very different, in certain cases they are actually equivalent. Let's consider an example. Let  $\psi: X \to \mathbb{R}$  and consider that case that  $\mathcal{V} = \mathcal{X} = \operatorname{dom} \psi$ . The output of OMD is

$$\boldsymbol{x}_{t+1} = \underset{\boldsymbol{x}}{\operatorname{argmin}} \langle \eta \boldsymbol{g}_t, \boldsymbol{x} \rangle + B_{\psi}(\boldsymbol{x}; \boldsymbol{x}_t) .$$

Assume that  $x_{t+1} \in \operatorname{int} \operatorname{dom} \psi$  for all t = 1, ..., T. This implies that  $\eta g_t + \nabla \psi(x_{t+1}) - \nabla \psi(x_t) = \mathbf{0}$ , that is  $\nabla \psi(x_{t+1}) = \nabla \psi(x_t) - \eta g_t$ . Assuming  $x_1 = \min_{x \in \mathcal{V}} \psi(x)$ , we have

$$\nabla \psi(\boldsymbol{x}_{t+1}) = -\eta \sum_{i=1}^{t} \boldsymbol{g}_{i} .$$

On the other hand, consider FTRL with linearized losses with regularizers  $\psi_t = \frac{1}{\eta} \psi$ , then

$$x_{t+1} = \underset{x}{\operatorname{argmin}} \frac{1}{\eta} \psi(x) + \sum_{i=1}^{t} \langle g_i, x \rangle = \underset{x}{\operatorname{argmin}} \psi(x) + \eta \sum_{i=1}^{t} \langle g_i, x \rangle.$$

Assuming that  $x_{t+1} \in \operatorname{int} \operatorname{dom} \psi$ , this implies that  $\nabla \psi(x_{t+1}) = -\eta \sum_{i=1}^t g_i$ . Further, assuming that  $\nabla \psi$  is invertible, implies that the predictions of FTRL and OMD are the same.

This equivalence immediately gives us some intuition on the role of  $\psi$  in both algorithm: The same function is inducing the Bregman divergence, that is our similarity measure, and is the regularizer in FTRL. Moreover, the inverse of the growth rate of the regularizers in FTRL takes the role of the learning rate in OMD.

**Example 7.14.** Consider  $\psi(x) = \frac{1}{2} ||x||_2^2$  and  $\mathcal{V} = \mathbb{R}^d$ , then it satisfies the conditions above to have the predictions of OMD equal to the ones of FTRL.

**Remark 7.15.** Based on the above observation and on the observations in Section 7.3, a common misunderstanding even among experts is that FTRL and OMD differs only in the constrained setting. This is clearly false: The regularizer of FTRL can vary over time in arbitrary ways, not just as a scaled version of a fixed regularizer. Indeed, general timevarying regularizers are used, for example, in Parameter-Free algorithms (Chapter 10).

### 7.4 FTRL Regret Bound using Local Norms

In Lemma 7.6, strong convexity basically tells us that the losses plus regularizer have some minimum curvature in all the directions. However, as in the OMD case, it turns out that we can get a regret upper bound using again the notion of local norms.

**Lemma 7.16.** Under the same assumptions of Lemma 7.1, assume  $\psi_1, \ldots, \psi_T$  twice differentiable and with the Hessian positive definite in the interior of their domains, and  $\psi_{t+1}(\mathbf{x}) \geq \psi_t(\mathbf{x}), \forall \mathbf{x} \in \mathcal{V}, t = 1, \ldots, T$ . Also, assume  $\ell_t(\mathbf{x}) = \langle \mathbf{g}_t, \mathbf{x} \rangle, \ t = 1, \ldots, T$ , for arbitrary vectors  $\mathbf{g}_t$ . Define  $\|\mathbf{x}\|_{\mathbf{A}} := \sqrt{\mathbf{x}^\top \mathbf{A} \mathbf{x}}$ . For  $t = 1, \ldots, T$ , assume that  $\mathbf{x}_t$ 

is in the interior of the domain of  $\psi_t$  and that  $\tilde{x}_{t+1} := \operatorname{argmin}_{x \in \mathbb{R}^d} \langle g_t, x \rangle + B_{\psi_t}(x; x_t)$  exists. Then, there exists  $z_t$  on the line segments between  $x_t$  and  $\tilde{x}_{t+1}$ , such that the following inequality holds for any  $u \in \mathcal{V}$ 

$$\sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{u} \rangle \leq \psi_{T+1}(\boldsymbol{u}) - \min_{\boldsymbol{x} \in \mathcal{V}} \psi_{1}(\boldsymbol{x}) + \sum_{t=1}^{T} \left[ \min \left( \frac{\|\boldsymbol{g}_{t}\|_{(\nabla^{2}\psi_{t}(\boldsymbol{z}_{t}))^{-1}}^{2}}{2}, \frac{\|\boldsymbol{g}_{t}\|_{(\nabla^{2}\psi_{t}(\boldsymbol{z}_{t}'))^{-1}}^{2}}{2} \right) + \psi_{t}(\boldsymbol{x}_{t+1}) - \psi_{t+1}(\boldsymbol{x}_{t+1}) \right].$$

*Proof.* We start from Lemma 7.1 and observe that

$$F_t(x_t) - F_{t+1}(x_{t+1}) + \ell_t(x_t) = F_t(x_t) - F_t(x_{t+1}) + \ell_t(x_t) - \ell_t(x_{t+1}) + \psi_t(x_{t+1}) - \psi_{t+1}(x_{t+1})$$
.

Then, observe that  $\psi_t$  are strictly convex because the Hessians are positive definite. Hence, they can be used to define Bregman divergences. Moreover, from the optimality condition of  $x_t$ , we have

$$\langle \nabla F_t(\boldsymbol{x}_t), \boldsymbol{v} - \boldsymbol{x}_t \rangle \geq 0, \ \forall \boldsymbol{v} \in \mathcal{V} .$$

Hence, in particular we have

$$\langle \nabla F_t(\boldsymbol{x}_t), \boldsymbol{x}_{t+1} - \boldsymbol{x}_t \rangle \geq 0$$
.

Using this inequality, we have

$$B_{F_t}(\boldsymbol{x}_{t+1}; \boldsymbol{x}_t) = F_t(\boldsymbol{x}_{t+1}) - F_t(\boldsymbol{x}_t) - \langle \nabla F_t(\boldsymbol{x}_t), \boldsymbol{x}_{t+1} - \boldsymbol{x}_t \rangle \le F_t(\boldsymbol{x}_{t+1}) - F_t(\boldsymbol{x}_t)$$
.

This last inequality implies that

$$F_t(x_t) - F_t(x_{t+1}) + \ell_t(x_t) - \ell_t(x_{t+1}) = F_t(x_t) - F_t(x_{t+1}) + \langle g_t, x_t - x_{t+1} \rangle \leq \langle g_t, x_t - x_{t+1} \rangle - B_{F_t}(x_{t+1}; x_t).$$

Bregman divergences are independent of linear terms, so  $B_{F_t}(\boldsymbol{x}_{t+1}; \boldsymbol{x}_t) = B_{\psi_t}(\boldsymbol{x}_{t+1}; \boldsymbol{x}_t)$ . From the Taylor's theorem, we have said that  $B_{\psi_t}(\boldsymbol{x}_{t+1}; \boldsymbol{x}_t) = \frac{1}{2}(\boldsymbol{x}_{t+1} - \boldsymbol{x}_t)^\top \nabla^2 \psi_t(\boldsymbol{z}_t)(\boldsymbol{x}_{t+1} - \boldsymbol{x}_t)$ , where  $\boldsymbol{z}_t$  is on the line segment between  $\boldsymbol{x}_t$  and  $\boldsymbol{x}_{t+1}$ . Observe that this is  $\frac{1}{2} \|\boldsymbol{x}_{t+1} - \boldsymbol{x}_t\|_{\nabla^2 \psi_t(\boldsymbol{z}_t)}^2$  and it is indeed a norm because we assumed the Hessian of  $\psi_t$  to be positive definite. Hence, by Fenchel-Young inequality and Examples 4.18 and 6.21, we have

$$F_{t}(\boldsymbol{x}_{t}) - F_{t}(\boldsymbol{x}_{t+1}) + \ell_{t}(\boldsymbol{x}_{t}) - \ell_{t}(\boldsymbol{x}_{t+1})$$

$$\leq \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{x}_{t+1} \rangle - B_{\psi_{t}}(\boldsymbol{x}_{t+1}; \boldsymbol{x}_{t})$$

$$\leq \frac{1}{2} \|\boldsymbol{g}_{t}\|_{(\nabla^{2}\psi_{t}(\boldsymbol{z}_{t}))^{-1}}^{2} + \frac{1}{2} (\boldsymbol{x}_{t+1} - \boldsymbol{x}_{t})^{\top} \nabla^{2} \psi_{t}(\boldsymbol{z}_{t}) (\boldsymbol{x}_{t+1} - \boldsymbol{x}_{t}) - B_{\psi_{t}}(\boldsymbol{x}_{t+1}; \boldsymbol{x}_{t})$$

$$= \frac{1}{2} \|\boldsymbol{g}_{t}\|_{(\nabla^{2}\psi_{t}(\boldsymbol{z}_{t}))^{-1}}^{2},$$

$$(7.2)$$

that gives the first term in the minimum.

For the second term in the minimum, we start from (7.2) to get

$$\langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{x}_{t+1} \rangle - B_{\psi_{t}}(\boldsymbol{x}_{t+1}; \boldsymbol{x}_{t}) \leq \max_{\boldsymbol{x} \in \mathbb{R}^{d}} \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{x} \rangle - B_{\psi_{t}}(\boldsymbol{x}; \boldsymbol{x}_{t})$$
$$= \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \tilde{\boldsymbol{x}}_{t+1} \rangle - B_{\psi_{t}}(\tilde{\boldsymbol{x}}_{t+1}; \boldsymbol{x}_{t}) .$$

Then, we proceed as in the first bound.

Observe as  $z_t'$  is defined as a sort of OMD update using  $\psi_t$  as distance generating function. Also, differently from the local norm bound for OMD,  $z_t'$  does not appear in the FTRL algorithm in any way.

### 7.5 Example of FTRL: Exponentiated Gradient without Knowing T

As we did in Section 6.6 for OMD, let's see an example of an instantiation of FTRL with linearized losses to have the FTRL version of Exponentiated Gradient.

Let  $\mathcal{V}=\{\boldsymbol{x}\in\mathbb{R}^d:\|\boldsymbol{x}\|_1=1,x_i\geq 0\}$  and the sequence of loss functions  $\ell_t:\mathcal{V}\to\mathbb{R}$  be convex and  $L_{\infty}$ -Lipschitz w.r.t. the  $L_{\infty}$  norm. Let  $\psi:R^d_{\geq 0}\to\mathbb{R}^d$  be defined as  $\psi(\boldsymbol{x})=\sum_{i=1}^d x_i\ln x_i$ , where we define  $0\ln 0=0$ . Set  $\psi_t(\boldsymbol{x})=\alpha L_{\infty}\sqrt{t}\psi(\boldsymbol{x})$ , that is  $\alpha L_{\infty}\sqrt{t}$ -strongly convex w.r.t. the  $L_1$  norm by Lemma 6.34, where  $\alpha>0$  is a parameter of the algorithm.

Given that the regularizers are strongly convex and defining  $\psi_{\mathcal{V},t} = \psi_t + i_{\mathcal{V}}$ , from (7.1) we have

$$\boldsymbol{x}_t = \nabla \psi_{\mathcal{V},t}^{\star} \left( -\sum_{i=1}^{t-1} \boldsymbol{g}_i \right) .$$

We already saw in Section 6.6 that  $\psi_{\mathcal{V}}^{\star}(\boldsymbol{\theta}) = \ln\left(\sum_{i=1}^{d} \exp(\theta_i)\right)$ , that implies that  $\psi_{\mathcal{V},t}^{\star}(\boldsymbol{\theta}) = \alpha L_{\infty} \sqrt{t} \ln\left(\sum_{i=1}^{d} \exp\left(\frac{\theta_i}{\alpha L_{\infty} \sqrt{t}}\right)\right)$ . So, running FTRL with linearized losses, we have that

$$x_{t,j} = \frac{\exp\left(-\frac{\sum_{k=1}^{t-1} g_{k,j}}{\alpha L_{\infty} \sqrt{t}}\right)}{\sum_{i=1}^{d} \exp\left(-\frac{\sum_{k=1}^{t-1} g_{k,i}}{\alpha L_{\infty} \sqrt{t}}\right)}, \ j = 1, \dots, d,$$

where  $g_t \in \partial \ell_t(x_t)$ . Note that this is exactly the same update of EG based on OMD, but here we are effectively using time-varying learning rates.

We also get that the regret guarantee is

$$\sum_{t=1}^{T} \ell_{t}(\boldsymbol{x}_{t}) - \sum_{t=1}^{T} \ell(\boldsymbol{u}) \leq L_{\infty} \sqrt{T} \alpha \left( \sum_{i=1}^{d} u_{i} \ln u_{i} + \ln d \right) + \frac{1}{2\alpha L_{\infty}} \sum_{t=1}^{T} \frac{\|\boldsymbol{g}_{t}\|_{\infty}^{2}}{\sqrt{t}}$$

$$\leq L_{\infty} \sqrt{T} \left( \alpha \left( \sum_{i=1}^{d} u_{i} \ln u_{i} + \ln d \right) + \frac{1}{\alpha} \right)$$

$$\leq L_{\infty} \sqrt{T} \left( \alpha \ln d + \frac{1}{\alpha} \right), \ \forall \boldsymbol{u} \in \mathcal{V},$$
(7.3)

where we used the fact that using  $\psi_t = \alpha L_\infty \sqrt{t} \psi(\boldsymbol{x})$  and  $\psi_t = \alpha L_\infty \sqrt{t} (\psi(\boldsymbol{x}) - \min_{\boldsymbol{x}} \psi(\boldsymbol{x}))$  are equivalent. The optimal choice of  $\alpha$  to minimize the regret upper bound is  $\frac{1}{\sqrt{\ln d}}$ . This regret guarantee is similar to the one we proved for OMD, but with an important difference: We do not have to know in advance the number of rounds T. In OMD a similar bound would be vacuous because it would depend on the  $\max_{\boldsymbol{u}, \boldsymbol{x} \in \mathcal{V}} B_{\psi}(\boldsymbol{u}; \boldsymbol{x})$  that is infinite.

As we did in the OMD case, we can also get a bound using the local norms. Let's use the additional assumption that  $g_{t,i} \ge 0$ , for all t = 1, ..., T and i = 1, ..., d. Using Lemma 7.16, we have for all  $u \in \mathcal{V}$  that

$$\sum_{t=1}^{T} \ell_{t}(\boldsymbol{x}_{t}) - \sum_{t=1}^{T} \ell(\boldsymbol{u}) \leq L_{\infty} \sqrt{T} \alpha \left( \sum_{i=1}^{d} u_{i} \ln u_{i} + \ln d \right) + \frac{1}{2} \sum_{t=1}^{T} \|\boldsymbol{g}_{t}\|_{(\nabla^{2} \psi_{t}(\boldsymbol{z}'_{t}))^{-1}}^{2}$$

$$= L_{\infty} \sqrt{T} \alpha \left( \sum_{i=1}^{d} u_{i} \ln u_{i} + \ln d \right) + \frac{1}{2\alpha L_{\infty}} \sum_{t=1}^{T} \frac{\|\boldsymbol{g}_{t}\|_{(\nabla^{2} \psi(\boldsymbol{z}'_{t}))^{-1}}^{2}}{\sqrt{t}},$$

where  $z_t'$  is on the line segment between  $x_t$  and  $\tilde{x}_{t+1}$ . In this case, it is easy to calculate  $\tilde{x}_{t+1,i}$  as  $x_{t,i} \exp(-\frac{g_{t,i}}{\alpha L_\infty \sqrt{t}})$  for  $i=1,\ldots,d$ . Moreover,  $\nabla^2 \psi(z_t')$  is a diagonal matrix whose elements on the diagonal are  $\frac{1}{z_{t,i}'}, i=1,\ldots,d$ . Hence, we have that

$$\|\boldsymbol{g}_{t}\|_{(\nabla^{2}\psi(\boldsymbol{z}'_{t}))^{-1}}^{2} = \sum_{i=1}^{d} g_{t,i}^{2} z'_{t,i} \le \sum_{i=1}^{d} g_{t,i}^{2} x_{t,i},$$

$$(7.4)$$

that is less than or equal to the terms  $\|g_t\|_{\infty}^2$  we have in (7.3).

### 7.6 Example of FTRL: AdaHedge\*

In this section, we explain a variation of the EG/Hedge algorithm, called AdaHedge. The basic idea is to design an algorithm that is adaptive to the sum of the squared  $L_{\infty}$  norm of the losses, without any prior information on the range of the losses.

First, consider the case in which we use as constant regularizer the negative entropy  $\psi_t(x) = \lambda \sum_{i=1}^d x_i \ln x_i$  defined over  $\mathbb{R}^d_{\geq 0}$ , where  $\lambda > 0$  will be determined in the following. Set  $\mathcal{V}$  to be the probability simplex in  $\mathbb{R}^d$ . Using FTRL with linear losses with this regularizer, we immediately obtain

$$\operatorname{Regret}_{T}(\boldsymbol{u}) \leq \lambda (\ln d + \sum_{i=1}^{d} u_{i} \ln u_{i}) + \sum_{t=1}^{T} (F_{t}(\boldsymbol{x}_{t}) - F_{t+1}(\boldsymbol{x}_{t+1}) + \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} \rangle)$$

$$\leq \lambda \ln d + \sum_{t=1}^{T} (F_{t}(\boldsymbol{x}_{t}) - F_{t+1}(\boldsymbol{x}_{t+1}) + \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} \rangle),$$

where we upper bounded the negative entropy of u with 0. Using the strong convexity of the regularizer w.r.t. the  $L_1$  norm and Lemma 7.6, we would further upper bound this as

$$\operatorname{Regret}_{T}(\boldsymbol{u}) \leq \lambda \ln d + \sum_{t=1}^{T} \frac{\|\boldsymbol{g}_{t}\|_{\infty}^{2}}{2\lambda}.$$

This suggests that the optimal  $\lambda$  should be  $\lambda = \sqrt{\frac{\sum_{t=1}^{T} \|g_t\|_{\infty}^2}{2 \ln d}}$ . However, as we have seen in Section 4.2, this choice of any parameter of the algorithm is never feasible. Hence, exactly as we did in Section 4.2, we might think of using an online version of this choice

$$\psi_t(\boldsymbol{x}) = \lambda_t \sum_{i=1}^d x_i \ln x_i \quad \text{where} \quad \lambda_t = \frac{1}{\alpha} \sqrt{\sum_{i=1}^{t-1} \|\boldsymbol{g}_i\|_{\infty}^2}, \tag{7.5}$$

where  $\alpha > 0$  is a constant that will be determined later. An important property of such choice is that it gives rise to an algorithm that is scale-free, that is its predictions  $x_t$  are invariant from the scaling of the losses by any constant factor. This is easy to see because

$$x_{t,j} \propto \exp\left(-\frac{\alpha \sum_{i=1}^{t-1} g_{i,j}}{\sqrt{\sum_{i=1}^{t-1} \|g_i\|_{\infty}^2}}\right), \ \forall i = 1, \dots, d.$$

Note that this choice makes the regularizer non-decreasing over time and immediately gives us

$$\operatorname{Regret}_{T}(\boldsymbol{u}) \leq \lambda_{T} \ln d + \sum_{t=1}^{T} \frac{\|\boldsymbol{g}_{t}\|_{\infty}^{2}}{2\lambda_{t}} = \frac{\ln d}{\alpha} \sqrt{\sum_{t=1}^{T} \|\boldsymbol{g}_{t}\|_{\infty}^{2}} + \alpha \sum_{t=1}^{T} \frac{\|\boldsymbol{g}_{t}\|_{\infty}^{2}}{2\sqrt{\sum_{i=1}^{t-1} \|\boldsymbol{g}_{i}\|_{\infty}^{2}}}.$$

At this point, we might be tempted to use Lemma 4.13 to upper bound the sum in the upper bound, but unfortunately we cannot! Indeed, the denominator does not contain the term  $\|\boldsymbol{g}_t\|_{\infty}^2$ . We might add a constant to  $\lambda_t$ , but that would destroy the scale-freeness of the algorithm. However, it turns out that we can still prove our bound without any change to the regularizer. The key observation is that we can bound the term  $F_t(\boldsymbol{x}_t) - F_{t+1}(\boldsymbol{x}_{t+1}) + \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle$  in two different ways. One way is using Lemma 7.6. The other one is

$$\begin{split} F_t(\boldsymbol{x}_t) - F_{t+1}(\boldsymbol{x}_{t+1}) + \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle &\leq F_t(\boldsymbol{x}_{t+1}) - F_{t+1}(\boldsymbol{x}_{t+1}) + \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle \\ &= \psi_t(\boldsymbol{x}_{t+1}) + \sum_{i}^{t-1} \langle \boldsymbol{g}_i, \boldsymbol{x}_{t+1} \rangle - \psi_{t+1}(\boldsymbol{x}_{t+1}) - \sum_{i=1}^{t} \langle \boldsymbol{g}_i, \boldsymbol{x}_{t+1} \rangle + \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle \\ &\leq -\langle \boldsymbol{g}_t, \boldsymbol{x}_{t+1} \rangle + \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle \\ &\leq 2 \|\boldsymbol{g}_t\|_{\infty}, \end{split}$$

where we used the definition of  $x_{t+1}$  and the fact that the regularizer is non-decreasing over time. So, we can now write

$$\begin{split} \sum_{t=1}^{T} F_{t}(\boldsymbol{x}_{t}) - F_{t+1}(\boldsymbol{x}_{t+1}) + \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} \rangle &\leq \sum_{t=1}^{T} \min \left( \frac{\alpha \|\boldsymbol{g}_{t}\|_{\infty}^{2}}{2\sqrt{\sum_{i=1}^{t-1} \|\boldsymbol{g}_{i}\|_{\infty}^{2}}}, 2\|\boldsymbol{g}_{t}\|_{\infty} \right) \\ &= 2 \sum_{t=1}^{T} \sqrt{\min \left( \frac{\alpha^{2} \|\boldsymbol{g}_{t}\|_{\infty}^{4}}{16 \sum_{i=1}^{t-1} \|\boldsymbol{g}_{i}\|_{\infty}^{2}}, \|\boldsymbol{g}_{t}\|_{\infty}^{2} \right)} \\ &\leq 2 \sum_{t=1}^{T} \sqrt{\frac{2}{\frac{16 \sum_{i=1}^{t-1} \|\boldsymbol{g}_{i}\|_{\infty}^{2}} + \frac{1}{\|\boldsymbol{g}_{t}\|_{\infty}^{2}}}} \\ &= 2 \sum_{t=1}^{T} \sqrt{2} \frac{\alpha \|\boldsymbol{g}_{t}\|_{\infty}^{2}}{\sqrt{\alpha^{2} \|\boldsymbol{g}_{t}\|_{\infty}^{2} + 16 \sum_{i=1}^{t-1} \|\boldsymbol{g}_{i}\|_{\infty}^{2}}}, \end{split}$$

where we used the fact that the minimum between two numbers is less than their harmonic mean. Assuming  $\alpha \geq 4$  and using Lemma 4.13, we have

$$\sum_{t=1}^{T} F_t(\boldsymbol{x}_t) - F_{t+1}(\boldsymbol{x}_{t+1}) + \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle \leq \frac{\sqrt{2}}{2} \sum_{t=1}^{T} \frac{\alpha \|\boldsymbol{g}_t\|_{\infty}^2}{\sqrt{\sum_{i=1}^{t} \|\boldsymbol{g}_i\|_{\infty}^2}} \leq \alpha \sqrt{2 \sum_{t=1}^{T} \|\boldsymbol{g}_t\|_{\infty}^2}$$

and

$$\operatorname{Regret}_{T}(\boldsymbol{u}) \leq \left(\frac{\ln d}{\alpha} + \alpha \sqrt{2}\right) \sqrt{\sum_{t=1}^{T} \|\boldsymbol{g}_{t}\|_{\infty}^{2}}.$$
 (7.6)

The bound and the assumption on  $\alpha$  suggest to set  $\alpha = \max(4, 2^{-1/4}\sqrt{\ln d})$ .

We might consider ourselves happy, but there is a clear problem in the above algorithm: the choice of  $\lambda_t$  in the time-varying regularizer strictly depend on our upper bound. So, a loose bound will result in a poor choice of the regularization! In general, every time we use a part of the proof in the design of an algorithm we cannot expect an exciting empirical performance, unless our upper bound was really tight. So, can we design a better regularizer? Well, we need a better upper bound!

Let's consider a generic regularizer  $\psi_t(x) = \lambda_t \psi(x)$  and its corresponding FTRL with linear losses regret upper bound

$$\operatorname{Regret}_{T}(\boldsymbol{u}) \leq \lambda_{T}(\psi(\boldsymbol{u}) - \inf_{\boldsymbol{x} \in \mathcal{V}} \psi(\boldsymbol{x})) + \sum_{t=1}^{T} \left( F_{t}(\boldsymbol{x}_{t}) - F_{t+1}(\boldsymbol{x}_{t+1}) + \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} \rangle \right),$$

where we assume  $\lambda_t$  to be non-decreasing in time.

Now, observe that the sum is unlikely to disappear for this kind of algorithms, so we could try to make the term  $\lambda_T(\psi(u) - \inf_{x \in \mathcal{V}} \psi(x))$  of the same order of the sum. So, we would like to set  $\lambda_t$  of the same order of  $\sum_{i=1}^t (F_i(x_i) - F_{i+1}(x_{i+1}) + \langle g_i, x_i \rangle)$ . However, this approach would cause an annoying recurrence. So, using the fact that  $\lambda_t$  is non-decreasing, let's upper bound the terms in the sum just a little bit:

$$F_{t}(\boldsymbol{x}_{t}) - F_{t+1}(\boldsymbol{x}_{t+1}) + \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} \rangle = F_{t}(\boldsymbol{x}_{t}) - \lambda_{t+1}\psi(\boldsymbol{x}_{t+1}) - \sum_{i=1}^{t} \langle \boldsymbol{g}_{i}, \boldsymbol{x}_{t+1} \rangle + \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} \rangle$$

$$\leq F_{t}(\boldsymbol{x}_{t}) - \lambda_{t}\psi(\boldsymbol{x}_{t+1}) - \sum_{i=1}^{t} \langle \boldsymbol{g}_{i}, \boldsymbol{x}_{t+1} \rangle + \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} \rangle$$

$$\leq F_{t}(\boldsymbol{x}_{t}) - \min_{\boldsymbol{x} \in \mathcal{V}} \left( \lambda_{t}\psi(\boldsymbol{x}) + \sum_{i=1}^{t} \langle \boldsymbol{g}_{i}, \boldsymbol{x} \rangle \right) + \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} \rangle := \delta_{t} .$$

Now, we can set  $\lambda_t = \frac{1}{\alpha^2} \sum_{i=1}^{t-1} \delta_i$  for  $t \geq 2$ ,  $\lambda_1 = 0$ , and  $\boldsymbol{x}_1 = \operatorname{argmin}_{\boldsymbol{x} \in \mathcal{V}} \psi(\boldsymbol{x})$ . This immediately implies that

$$\operatorname{Regret}_{T}(\boldsymbol{u}) \leq \left(\psi(\boldsymbol{u}) - \inf_{\boldsymbol{x} \in \mathcal{V}} \psi(\boldsymbol{x}) + \alpha^{2}\right) \lambda_{T+1}.$$

Setting  $\psi$  to be equal to the negative entropy, we get an algorithm known as AdaHedge.

With this choice of the regularizer, we can simplify a bit the expression of  $\delta_t$ . For t=1, we have  $\delta_1=\langle \boldsymbol{g}_1,\boldsymbol{x}_1\rangle$  –  $\min_{x \in \mathcal{V}} \langle g_1, x \rangle$ . Instead, for  $t \geq 2$ , using the properties of the Fenchel conjugates, we have that

$$\delta_t = \lambda_t \ln \frac{\sum_{j=1}^d \exp\left(\theta_{t+1,j}/\lambda_t\right)}{\sum_{j=1}^d \exp\left(\theta_{t,j}/\lambda_t\right)} + \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle = \lambda_t \ln \left(\sum_{j=1}^d x_{t,j} \exp\left(-g_{t,j}/\lambda_t\right)\right) + \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle.$$

Overall, we get the pseudo-code of AdaHedge in Algorithm 7.3.

#### Algorithm 7.3 AdaHedge Algorithm

```
Require: \alpha > 0
```

1:  $\lambda_1 = 0$ 

2:  $\boldsymbol{x}_1 = [1/d,\ldots,1/d] \in \mathbb{R}^d$ 3:  $\boldsymbol{\theta}_1 = \mathbf{0} \in \mathbb{R}^d$ 

4: for t = 1 to T do

Output  $\boldsymbol{x}_t$ 

Receive  $\boldsymbol{g}_t \in \mathbb{R}^d$  and pay  $\langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle$ 

8: Set 
$$\delta_t = \begin{cases} \langle \boldsymbol{g}_1, \boldsymbol{x}_1 \rangle - \min_{j=1,\dots,d} \ g_{t,j}, & t = 1 \\ \lambda_t \ln \left( \sum_{j=1}^d x_{t,j} \exp\left(-g_{t,j}/\lambda_t\right) \right) + \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle, & \text{otherwise} \end{cases}$$

Update  $\lambda_{t+1} = \lambda_t + \frac{1}{\alpha^2} \delta_t$ 

Update  $x_{t+1,j} \propto \exp\left(\frac{\theta_{t+1,j}}{\lambda_{t+1}}\right), j = 1, \dots, d$ 

11: end for

So, now we need an upper bound for  $\lambda_T$ . Observe that  $\lambda_{t+1} = \lambda_t + \frac{1}{\alpha^2} \delta_t$ . Moreover, as we have done before, we can upper bound  $\delta_t$  in two different ways. In fact, from Lemma 7.6, we have  $\delta_t \leq \frac{\|g_t\|_{\infty}^2}{2\lambda_t}$  for  $t \geq 2$ . Also, denoting by  $ilde{m{x}}_{t+1} = \operatorname{argmin}_{m{x} \in \mathcal{V}} \ \lambda_t \psi(m{x}) + \sum_{i=1}^t \langle m{g}_i, m{x} 
angle,$  we have

$$\begin{split} \delta_t &= F_t(\boldsymbol{x}_t) - \min_{\boldsymbol{x} \in \mathcal{V}} \left( \lambda_t \psi(\boldsymbol{x}) + \sum_{i=1}^t \langle \boldsymbol{g}_i, \boldsymbol{x} \rangle \right) + \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle = F_t(\boldsymbol{x}_t) - \lambda_t \psi(\tilde{\boldsymbol{x}}_{t+1}) - \sum_{i=1}^t \langle \boldsymbol{g}_i, \tilde{\boldsymbol{x}}_{t+1} \rangle + \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle \\ &\leq F_t(\tilde{\boldsymbol{x}}_{t+1}) - \lambda_t \psi(\tilde{\boldsymbol{x}}_{t+1}) - \sum_{i=1}^t \langle \boldsymbol{g}_i, \tilde{\boldsymbol{x}}_{t+1} \rangle + \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle = -\langle \boldsymbol{g}_t, \tilde{\boldsymbol{x}}_{t+1} \rangle + \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle \leq 2 \|\boldsymbol{g}_t\|_{\infty} \;. \end{split}$$

Hence, we have

$$\begin{split} &\lambda_1 = 0, \\ &\lambda_2 \leq 2\alpha \|\boldsymbol{g}_1\|_{\infty}, \\ &\lambda_{t+1} = \lambda_t + \frac{\delta_t}{\alpha^2} \leq \lambda_t + \frac{1}{\alpha^2} \min\left(2\|\boldsymbol{g}_t\|_{\infty}, \frac{\|\boldsymbol{g}_t\|_{\infty}^2}{2\lambda_t}\right), \ \forall t \geq 2 \ . \end{split}$$

We can solve this recurrence using the following Lemma, where  $\Delta_t = \lambda_t$  and  $a_t = \|\boldsymbol{g}_t\|_{\infty}$ .

**Lemma 7.17.** Let  $\{a_t\}_{t=1}^{\infty}$  be any sequence of non-negative real numbers. Suppose that  $\{\Delta_t\}_{t=0}^{\infty}$  is a sequence of non-negative real numbers satisfying

$$\Delta_0 = 0 \qquad \text{and} \qquad \Delta_t \leq \Delta_{t-1} + \min \left\{ ba_t, \ c \frac{a_t^2}{2\Delta_{t-1}} \right\} \quad \text{for any } t \geq 1 \ .$$

Then, for any  $T \geq 0$ ,  $\Delta_T \leq \sqrt{(b^2 + c) \sum_{t=1}^T a_t^2}$ .

Proof. Observe that

$$\Delta_T^2 = \sum_{t=1}^T (\Delta_t^2 - \Delta_{t-1}^2) = \sum_{t=1}^T \left[ (\Delta_t - \Delta_{t-1})^2 + 2(\Delta_t - \Delta_{t-1})\Delta_{t-1} \right].$$

We bound each term in the sum separately. The left term of the minimum inequality in the definition of  $\Delta_t$  gives  $(\Delta_t - \Delta_{t-1})^2 \leq b^2 a_t^2$ , while the right term gives  $2(\Delta_t - \Delta_{t-1})\Delta_{t-1} \leq ca_t^2$ . So, we conclude  $\Delta_T^2 \leq (b^2 + c)\sum_{t=1}^T a_t^2$ .  $\square$ 

So, overall we got

$$\operatorname{Regret}_{T}(\boldsymbol{u}) \leq \left(\psi(\boldsymbol{u}) - \inf_{\boldsymbol{x} \in \mathcal{V}} \psi(\boldsymbol{x}) + \alpha^{2}\right) \lambda_{T+1} \leq \left(\frac{\psi(\boldsymbol{u}) - \inf_{\boldsymbol{x} \in \mathcal{V}} \psi(\boldsymbol{x})}{\alpha^{2}} + 1\right) \sqrt{(4 + \alpha^{2}) \sum_{t=1}^{T} \|\boldsymbol{g}_{t}\|_{\infty}^{2}},$$

and setting  $\alpha = \sqrt{\ln d}$ , we have

Regret<sub>T</sub>(
$$u$$
)  $\leq 2\sqrt{(4 + \ln d) \sum_{t=1}^{T} ||g_t||_{\infty}^{2}}$ .

Note that this is roughly the same regret in (7.6), but the very important difference is that this new regret bound depends on the much tighter quantity  $\lambda_{T+1}$ , that we upper bounded with a term proportional to  $\sqrt{\sum_{t=1}^{T} \|\boldsymbol{g}_t\|_{\infty}^2}$ , but in general it will be much smaller than that. For example,  $\lambda_{T+1}$  could be upper bounded using the tighter local norms, see Section 7.5. Instead, in the first solution, the regret will always be dominated by the term  $\sqrt{\sum_{t=1}^{T} \|\boldsymbol{g}_t\|_{\infty}^2}$  because we explicitly use it in the regularizer.

There is an important lesson to be learned from AdaHedge: the regret is not the full story and algorithms with the same worst-case guarantee can exhibit vastly different empirical behaviours. Unfortunately, this message is rarely heard and there is a part of the community that focuses too much on the worst-case guarantee rather than on the empirical performance. Even worse, sometimes people favor algorithms with a "more elegant analysis" completely ignoring the likely worse empirical performance.

# 7.7 Example of FTRL: Group Norms

Suppose you want to want to do linear regression and you have n different groups of features in  $\mathbb{R}^d$  associated to each sample. For example, they could represent different modalities (audio, video, etc.) associated to the same sample. You could just concatenate all the features in a long vector and learn with them using FTRL with a squared  $L_2$  regularizer. In alternative, we could use FTRL with p-norm (see Exercise 7.8), and tune p to have a logarithmic dependency on n d. However, there is something in between: We may want to learn a linear combination of predictors, one on each group, trying to use a very large number of groups and paying a small price for it. In particular, we might not want d to appear in the bound because it might be arbitrarily large, potentially infinity. This is the equivalent of the learning with experts setting, where each expert now is a linear predictor. In fact, one might be tempted to use one online learning algorithm on each group and a learning with experts algorithm on top that combines the predictions. However, this approach is very clunky because the learning with expert algorithm and the linear predictors are learning somehow independently, hence we can do much better. In fact, we can use an  $L_2$  norm over each group and a p-norm over the groups with p very close to 1. In this way, we expect a regret upper bound that depends on the maximum  $L_2$  norm of the subgradients w.r.t. each single group, but no explicit dependency in p. Let's see how this would work.

First, we introduce the definition of *group norms*.

**Definition 7.18** (Group Norm). Let  $X = \begin{bmatrix} x_1 & x_2 & \dots & x_n \end{bmatrix}$  be a  $d \times n$  real matrix with columns  $x_i \in \mathbb{R}^d$ . Given norms  $\Psi$  and  $\Phi$  on  $\mathbb{R}^d$  and  $\mathbb{R}^n$ , we define the **group norm**  $\|X\|_{\Psi,\Phi}$  as

$$\|X\|_{\Psi,\Phi} := \Phi([\Psi(x_1), \dots, \Psi(x_n)])$$
.

#### **Algorithm 7.4** FTRL with Group Norms for Linear Regression

**Require:**  $q > 0, \alpha > 0$ 

- 1:  $\boldsymbol{\theta}_{1,i} = \mathbf{0} \in \mathbb{R}^d, \ i = 1, \dots, n$
- 2: for t = 1 to T do
- Receive matrix of features  $Z_t = \begin{bmatrix} z_{t,1} & \dots & z_{t,n} \end{bmatrix}$
- Predict  $\hat{y}_t = \sum_{i=1}^n \boldsymbol{z}_{t,i}^{\top} \boldsymbol{x}_{t,i}$ Receive label  $y_t$  and pay  $|\hat{y}_t y_t|$
- Update  $\boldsymbol{\theta}_{t+1,i} = \boldsymbol{\theta}_{t,i} \boldsymbol{z}_{t,i} \operatorname{sign}(\hat{y}_t y_t), \ i = 1, \dots, n$ Update  $\boldsymbol{x}_{t+1,i} = \frac{\boldsymbol{\theta}_{t+1,i} \|\boldsymbol{\theta}_{t+1,i}\|_2^{q-2}}{\alpha \sqrt{t} (\sum_{j=1}^n \|\boldsymbol{\theta}_{t+1,j}\|_2^q)^{2/q}}, \ i = 1, \dots, n$
- 8: end for

It is possible to check that this is indeed a norm and we can also calculate the dual norm. We will need an additional definition.

**Definition 7.19** (Absolutely Symmetric Function). We say that  $f: \mathbb{R}^d \to \mathbb{R}$  is absolutely symmetric if it is invariant under permutations and sign changes of the components of its input.

**Lemma 7.20** ([Kakade et al., 2009, Lemma 17]). Let  $\Phi$  be an absolutely symmetric norm on  $\mathbb{R}^n$ . Then,

$$(\|\cdot\|_{\Psi,\Phi})_{\star} = \|\cdot\|_{\Psi^{\star},\Phi^{\star}}$$
.

From this Lemma and Example 6.21, we immediate have that the Fenchel conjugate of  $\frac{1}{2} \| \cdot \|_{\Psi,\Phi}^2$  is  $\frac{1}{2} \| \cdot \|_{\Psi^*,\Phi^*}^2$ . We can also construct strongly convex functions based on group norms.

**Theorem 7.21** ([Kakade et al., 2009, Theorem 18]). Let  $\Psi, \Phi$  be absolutely symmetric norms on  $\mathbb{R}^d$ ,  $\mathbb{R}^n$ . Let  $\Phi^2 \circ \mathcal{A}$ :  $\mathbb{R}^n \to (-\infty, +\infty]$  denote the following function,

$$(\Phi^2 \circ \sqrt{})(\boldsymbol{x}) := \Phi^2(\sqrt{x_1}, \dots, \sqrt{x_n})$$
.

Suppose,  $\Phi^2 \circ \sqrt{}$  is a norm on  $\mathbb{R}^n_{>0}$ . Further, let the functions  $\Psi^2$  and  $\Phi^2$  be  $\lambda_1$ - and  $\lambda_2$ -smooth w.r.t.  $\Psi$  and  $\Phi$ respectively. Then,  $\|\cdot\|_{\Psi,\Phi}^2$  is  $(\lambda_1 + \lambda_2)$ -smooth w.r.t.  $\|\cdot\|_{\Psi,\Phi}$ .

We can now specialize this result to group p-norms.

**Corollary 7.22.** Let  $q, s \geq 2$ . The function  $\frac{1}{2} \| \cdot \|_{q,s}^2$  is (q+s-2)-smooth w.r.t.  $\| \cdot \|_{q,s}$  on  $\mathbb{R}^{d \times n}$ .

Assuming  $n \geq 2$ , the above suggests to use FTRL with linearized losses and regularizer  $\psi_t(\boldsymbol{X}) = \frac{\alpha \sqrt{t}}{2} \|\boldsymbol{X}\|_{2,p}^2$ , where  $1 and <math>\alpha > 0$  will be decided in the following. From the above and Example 6.21, the dual is  $\psi_t^{\star}(\Theta) = \frac{1}{2\alpha\sqrt{t}} \|\Theta\|_{2,q}^2$  and it is  $\frac{q}{\alpha\sqrt{t}}$ -smooth, where  $\frac{1}{p} + \frac{1}{q} = 1$ . Moreover,

$$[\nabla \psi_t^{\star}(\mathbf{\Theta})]_i = \frac{\boldsymbol{\theta}_i \|\boldsymbol{\theta}_i\|_2^{q-2}}{\alpha \sqrt{t} (\sum_{j=1}^n \|\boldsymbol{\theta}_j\|_2^q)^{1-2/q}}, \ i = 1, \dots, n.$$

For simplicity, we will use the absolute loss as loss function. We are now ready to introduce Algorithm 7.4. From the analysis of FTRL with linearized losses, the properties of the group norms above, and Theorem 6.28, it is immediate to state a regret upper bound. With the notation in Algorithm 7.4, for any  $U \in \mathbb{R}^{d \times n}$  we have

$$\sum_{t=1}^{T} |\hat{y}_t - y_t| - \sum_{t=1}^{T} \left| \sum_{i=1}^{n} \boldsymbol{z}_t^{\top} \boldsymbol{u}_i - y_t \right| \leq \frac{\alpha \sqrt{T}}{2} \|\boldsymbol{U}\|_{2,p}^2 + \frac{q}{2\alpha} \sum_{t=1}^{T} \frac{\|\boldsymbol{Z}_t\|_{2,q}^2}{\sqrt{t}} \leq \frac{\alpha \sqrt{T}}{2} \|\boldsymbol{U}\|_{2,p}^2 + \frac{q\sqrt{T}}{\alpha} \max_{t \leq T} \|\boldsymbol{Z}_t\|_{2,q}^2.$$

To obtain a logarithmic dependency in n, we can now proceed as in Section 6.6. Assuming  $\|\boldsymbol{z}_{t,i}\|_2 \leq L$ , we have that  $\|\boldsymbol{Z}_t\|_{2,q}^2 \leq L^2 n^{2/q}$ . Hence, setting  $\alpha = qLn^{1/q}$  and  $q = \max(2\ln n, 2)$  we have that  $\frac{q}{\alpha}\|\boldsymbol{Z}_t\|_{2,q}^2 \leq L^2 n^{2/q}$ .  $L \max(\sqrt{2e \ln n}, 2)$ . Moreover, we can upper bound  $\|U\|_{2,p}^2$  with  $\|U\|_{2,1}^2$ . Hence, the final regret upper bound is  $L \max(\sqrt{2e \ln n}, 2) \left( \frac{\|U\|_{2,1}^2}{2} + 1 \right) \sqrt{T}$ , that is logarithmic in the number of groups.

### 7.8 Composite Losses and Proximal Operators

Let's now see a variant of the linearization of the losses: partial linearization of composite losses.

Suppose that the losses we receive are composed by two terms: one convex function changing over time and another part is fixed and known. These losses are called *composite*. For example, we might have  $\ell_t(x) = \tilde{\ell}_t(x) + \lambda ||x||_1$ . Using the linearization, we might just take the subgradient of  $\ell_t$ . However, in this particular case, we might lose the ability of the  $L_1$  norm to produce sparse solutions.

There is a better way to deal with these kind of losses: Move the constant part of the loss inside the regularization term. In this way, that part will not be linearized but used exactly in the argmin of the update. Moreover, the regret of the algorithm will depend only on the subgradient of  $\tilde{\ell}_t$  rather than subgradients of the full loss  $\ell_t$ . Assuming that the argmin is still easily computable, you can always expect better performance from this approach. In particular, in the case of adding an  $L_1$  norm to the losses, you will be predicting in each step with the solution of an  $L_1$  regularized optimization problem.

**Remark 7.23.** Given that we do not pay for the gradient of the regularizer in the regret upper bound of FTRL, one may wonder why we do not put the entire loss function in the regularizer. This is not possible because it would require knowledge of the future: at time t we construct the regularizer  $\psi_t$  when we do not have access to the future loss  $\ell_t$ .

Practically speaking, in the example above, we will define  $\psi_t(\boldsymbol{x}) = \frac{L}{\alpha} \sqrt{t} (\psi(\boldsymbol{x}) - \min_{\boldsymbol{y}} \psi(\boldsymbol{y})) + \lambda t \|\boldsymbol{x}\|_1$ , where we assume  $\psi$  to be 1-strongly convex and the losses  $\tilde{\ell}_t$  be L-Lipschitz. Note that we use at time t a term  $\lambda t \|\boldsymbol{x}\|_1$  because we anticipate the next term in the next round. Given that  $\psi_t(\boldsymbol{x}) + \sum_{i=1}^{t-1} \ell_t(\boldsymbol{x})$  is  $\frac{L}{\alpha} \sqrt{t}$ -strongly convex, using Lemma 7.6 and setting  $\psi_{T+1} = \psi_T$ , we have

$$\begin{split} &\sum_{t=1}^{T} \tilde{\ell}_{t}(\boldsymbol{x}_{t}) - \sum_{t=1}^{T} \tilde{\ell}_{t}(\boldsymbol{u}) \leq \sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} \rangle - \sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{u} \rangle \\ &\leq \frac{L}{\alpha} \sqrt{T} \left( \psi(\boldsymbol{u}) - \min_{\boldsymbol{x} \in \mathcal{V}} \psi(\boldsymbol{x}) \right) + \lambda T \|\boldsymbol{u}\|_{1} - \min_{\boldsymbol{x} \in \mathcal{V}} \left[ \lambda \|\boldsymbol{x}\|_{1} + L(\psi(\boldsymbol{x}) - \min_{\boldsymbol{y} \in \mathcal{V}} \psi(\boldsymbol{y})) \right] + \frac{\alpha}{2} \sum_{t=1}^{T} \frac{\|\boldsymbol{g}_{t}\|_{\star}^{2}}{L\sqrt{t}} - \lambda \sum_{t=1}^{T-1} \|\boldsymbol{x}_{t+1}\|_{1} \\ &\leq L\sqrt{T} \left( \alpha + \frac{\psi(\boldsymbol{u}) - \min_{\boldsymbol{x} \in \mathcal{V}} \psi(\boldsymbol{x})}{\alpha} \right) + \lambda T \|\boldsymbol{u}\|_{1} - \lambda \|\boldsymbol{x}_{1}\|_{1} - \lambda \sum_{t=1}^{T-1} \|\boldsymbol{x}_{t+1}\|_{1} \\ &= L\sqrt{T} \left( \alpha + \frac{\psi(\boldsymbol{u}) - \min_{\boldsymbol{x} \in \mathcal{V}} \psi(\boldsymbol{x})}{\alpha} \right) + \lambda T \|\boldsymbol{u}\|_{1} - \lambda \sum_{t=1}^{T} \|\boldsymbol{x}_{t}\|_{1}, \end{split}$$

where  $g_t \in \partial \tilde{\ell}_t(x_t)$ . Reordering the terms, we have

$$\sum_{t=1}^{T} \ell_t(\boldsymbol{x}_t) - \sum_{t=1}^{T} \ell_t(\boldsymbol{u}) = \sum_{t=1}^{T} (\lambda \|\boldsymbol{x}_t\|_1 + \tilde{\ell}_t(\boldsymbol{x}_t)) - \sum_{t=1}^{T} (\lambda \|\boldsymbol{u}\|_1 + \tilde{\ell}_t(\boldsymbol{u})) \le L\sqrt{T} \left( \frac{\psi(\boldsymbol{u}) - \min_{\boldsymbol{x} \in \mathcal{V}} \psi(\boldsymbol{x})}{\alpha} + \alpha \right) .$$

**Example 7.24.** Let's also take a look at the update rule in that case that  $\psi(\mathbf{x}) = \frac{1}{2} \|\mathbf{x}\|_2^2$  and we get composite losses with the  $L_1$  norm. Also, assume that  $\mathcal{V} = \mathbb{R}^d$ . So, we have

$$oldsymbol{x}_t = \operatorname*{argmin}_{oldsymbol{x} \in \mathbb{R}^d} \ rac{L\sqrt{t}}{2lpha} \|oldsymbol{x}\|_2^2 + \lambda t \|oldsymbol{x}\|_1 + \sum_{i=1}^{t-1} \langle oldsymbol{g}_i, oldsymbol{x} 
angle \ .$$

We can solve this problem observing that the minimization decomposes over each coordinate of x. Denote by  $\theta_t = \sum_{i=1}^{t-1} g_i$ . Hence, we know from first-order optimality condition in Theorem 6.29 that  $x_{t,i}$  is the solution for the coordinate i iff there exists  $v_i \in \partial |x_{t,i}|$  such that

$$\frac{L}{\alpha}\sqrt{t}x_{t,i} + \lambda tv_i + \theta_{t,i} = 0.$$

The difficulty comes from the fact that v is a subgradient in the next point  $x_t$ , that we do not know because we do not know v. Unfortunately there is no automatic way to find  $v_i$ , so we can "guess" the correct expression of  $v_i$  and verify its correctness in the above expression. In particular, considering 3 different cases, we have

- $|\theta_{t,i}| \leq \lambda t$ , then  $x_{t,i} = 0$  and  $v_i = -\frac{\theta}{\lambda t}$ .
- $\theta_{t,i} > \lambda t$ , then  $x_{t,i} = -\alpha \frac{\theta_{t,i} \lambda t}{L\sqrt{t}}$  and  $v_i = -1$ .
- $\theta_{t,i} < -\lambda t$ , then  $x_{t,i} = -\alpha \frac{\theta_{t,i} + \lambda t}{L\sqrt{t}}$  and  $v_i = 1$ .

So, overall we have

$$x_{t,i} = -\alpha \frac{\operatorname{sign}(\theta_{t,i}) \max(|\theta_{t,i}| - \lambda t, 0)}{L\sqrt{t}}.$$

Observe as this update will produce sparse solutions, while just taking the subgradient of the  $L_1$  norm would have never produced sparse predictions.

In the example above, we calculated something like

$$\underset{\boldsymbol{x} \in \mathbb{R}^d}{\operatorname{argmin}} \ \|\boldsymbol{x}\|_1 - \langle \boldsymbol{v}, \boldsymbol{x} \rangle + \frac{1}{2} \|\boldsymbol{x}\|_2^2 = \underset{\boldsymbol{x} \in \mathbb{R}^d}{\operatorname{argmin}} \ \|\boldsymbol{x}\|_1 - \langle \boldsymbol{v}, \boldsymbol{x} \rangle + \frac{1}{2} \|\boldsymbol{x}\|_2^2 + \frac{1}{2} \|\boldsymbol{v}\|_2^2 = \underset{\boldsymbol{x} \in \mathbb{R}^d}{\operatorname{argmin}} \ \|\boldsymbol{x}\|_1 + \frac{1}{2} \|\boldsymbol{x} - \boldsymbol{v}\|_2^2 \ .$$

This operation is known in the optimization literature as *Proximal Operator* of the  $L_1$  norm. In general, a proximal operator of a convex, proper, and closed function  $f: \mathbb{R}^d \to (-\infty, +\infty]$  is defined as

$$\operatorname{Prox}_{f}(\boldsymbol{v}) = \underset{\boldsymbol{x} \in \mathbb{R}^d}{\operatorname{argmin}} f(\boldsymbol{x}) + \frac{1}{2} \|\boldsymbol{x} - \boldsymbol{v}\|_{2}^{2}. \tag{7.7}$$

Proximal operators are used in optimization in the same way as we used it: They allow to minimize the entire function rather a linear approximation of it. Also, proximal operators generalize the concept of Euclidean projection. Indeed,  $\text{Prox}_{i\nu}(v) = \Pi_{\mathcal{V}}(v)$ .

From the definition, we also derive the important property of proximal operators that they minimize the function in each update. In other words, if  $x_{t+1} = \operatorname{Prox}_f(x_t)$ , then  $f(x_{t+1}) \leq f(x_t)$ . Another interesting property is the fact that we can write the proximal operator as an *implicit* subgradient descent update. Let  $\eta > 0$  and consider the following update

$$oldsymbol{x}_{t+1} = \operatorname{Prox}_{\eta f}(oldsymbol{x}_t) = \operatorname*{argmin}_{oldsymbol{x} \in \mathbb{R}^d} \, \eta f(oldsymbol{x}) + rac{1}{2} \|oldsymbol{x} - oldsymbol{x}_t\|_2^2 \, .$$

Then, from Theorem 6.29 we have

$$\boldsymbol{x}_{t+1} = \boldsymbol{x}_t - \eta \boldsymbol{g}_t,$$

where  $g_t \in \partial f(x_{t+1})$ . Hence, we do an update step using the subgradient in the *next* iteration. This also reveals a connection between OMD and proximal updates. Indeed, the update in (7.7) resembles the one in (6.3), where the function is not linearized. We will use this kind of updates in Section 12.6.

### 7.9 FTRL on Strongly Convex Functions

We will now use Lemma 7.6 to prove a logarithmic regret bound for FTL with strongly convex losses. Note that the existence of unicity of  $x_t$  is guaranteed by Theorem 6.9.

**Corollary 7.25.** Let  $\ell_t: V \to \mathbb{R}$  be  $\mu_t$ -strongly convex w.r.t.  $\|\cdot\|$ , closed, and dom  $\partial \ell_t \neq \{\}$  for  $t = 1, \ldots, T$ . Set the sequence of regularizers to zero. Then, FTL guarantees a regret of

$$\sum_{t=1}^T \ell(\boldsymbol{x}_t) - \sum_{t=1}^T \ell_t(\boldsymbol{u}) \leq \frac{1}{2} \sum_{t=1}^T \frac{\|\boldsymbol{g}_t\|_\star^2}{\sum_{t=1}^t \mu_i}, \ \forall \boldsymbol{u} \in \mathcal{V}, \ \forall \boldsymbol{g}_t \in \partial \ell_t(\boldsymbol{x}_t) \ .$$

The above regret guarantee is the same of OMD over strongly convex losses, but here we do not need to know the strong convexity of the losses. In fact, we just need to output the minimizer over the past losses. However, this might be undesirable because now each update requires the minimization of a convex function.

### Algorithm 7.5 Follow-the-Regularized-Leader Algorithm with "Quadratized" Losses

**Require:** A sequence of regularizers  $\psi_1, \dots, \psi_T : \mathcal{X} \to \mathbb{R}$ , closed non-empty convex set  $\mathcal{V} \subseteq \mathcal{X} \subseteq \mathbb{R}^d$ 

- Output  $\boldsymbol{x}_t \in \operatorname{argmin}_{\boldsymbol{x} \in \mathcal{V}} \ \psi_t(\boldsymbol{x}) + \sum_{i=1}^{t-1} \left( \langle \boldsymbol{g}_i, \boldsymbol{x} \rangle + \frac{\mu_i}{2} \| \boldsymbol{x} \boldsymbol{x}_i \|^2 \right)$ Pay  $\ell_t(\boldsymbol{x}_t)$  for  $\ell_t : \mathcal{V} \to \mathbb{R}$  subdifferentiable in  $\mathcal{V}$  and  $\mu_t$  strongly convex
- 5: end for

Hence, we can again use the idea of replacing the losses with simpler *surrogates*. In the Lipschitz case, it made sense to use linear losses because they were used to upper bound the regret of the true losses. However, here you can do better and use quadratic losses, because the losses are strongly convex. In fact, assuming  $\ell_t$  to be  $\mu_t$  strongly convex w.r.t.  $\|\cdot\|$ , we have

$$\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u}) \le \langle \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{u} \rangle - \frac{\mu_t}{2} \|\boldsymbol{x}_t - \boldsymbol{u}\|^2 = \tilde{\ell}_t(\boldsymbol{x}_t) - \tilde{\ell}_t(\boldsymbol{u}), \ \forall \boldsymbol{g}_t \in \partial \ell_t(\boldsymbol{x}_t).$$

So, we could run FTRL on the quadratic losses  $\tilde{\ell}_t(x) = \langle g_t, x \rangle + \frac{\mu_t}{2} ||x - x_t||^2$ , where  $g_t \in \partial \ell_t(x_t)$ . Depending on the norm, these quadratic losses might be strongly convex allowing us to use Corollary 7.25 and obtaining Algorithm 7.5.

For example, consider the case that the losses are strongly convex w.r.t. the  $L_2$  norm and there is no regularizer. Using Theorem 6.32, the update in Algorithm 7.5 becomes

$$x_{t} = \underset{x \in \mathcal{V}}{\operatorname{argmin}} \sum_{i=1}^{t-1} \left( \langle \boldsymbol{g}_{i}, \boldsymbol{x} \rangle + \frac{\mu_{i}}{2} \| \boldsymbol{x} - \boldsymbol{x}_{i} \|_{2}^{2} \right) = \Pi_{\mathcal{V}} \left( \frac{\sum_{i=1}^{t-1} (\mu_{i} \boldsymbol{x}_{i} - \boldsymbol{g}_{i})}{\sum_{i=1}^{t-1} \mu_{i}} \right), \tag{7.8}$$

where the only expensive operation is the projection, that can be computed in polynomial time. Moreover, we will get exactly the same regret bound as in Corollary 7.25 because  $g_t \in \partial \ell_t(x_t)$ . However, there are two important differences: 1) here the guarantee holds for a specific choice of the  $g_t$  rather than for any subgradient in  $\partial \ell_t(x_t)$ ; 2) we need to know the strong convexity parameters  $\mu_i$ , while it was not needed for FTL with exact losses.

**Example 7.26.** Going back to the example in the first chapter, where  $\mathcal{V} = [0,1]$  and  $\ell_t(\mathbf{x}) = (x-y_t)^2$  are strongly convex, we now see immediately that FTRL without a regularizer, that is Follow the Leader, gives logarithmic regret.

#### 7.10 A Weaker Notion of Strong Convexity and the Online Newton Step

In the previous section, we saw that the notion of strong convexity allows us to build quadratic surrogate loss functions, on which FTRL has smaller regret. Can we find a more general notion of strong convexity that allows to get a small regret for a larger class of functions? We can start from strong convexity and try to generalize it. So, instead of asking that the function is strongly convex w.r.t. a norm, we might be happy requiring strong convexity holds in a particular point w.r.t. a seminorm that depends on the points itself.

In particular, we can require that for each loss  $\ell_t: V \to \mathbb{R}$  the following holds

$$\forall \boldsymbol{x} \in \mathcal{V}, \boldsymbol{g} \in \partial \ell_t(\boldsymbol{x}), \exists \boldsymbol{A}_t \in \mathbb{R}^{d \times d} : \boldsymbol{A}_t \succeq 0, \ \ell_t(\boldsymbol{y}) \ge \ell_t(\boldsymbol{x}) + \langle \boldsymbol{g}, \boldsymbol{y} - \boldsymbol{x} \rangle + \frac{1}{2} \|\boldsymbol{x} - \boldsymbol{y}\|_{\boldsymbol{A}_t}^2, \forall \boldsymbol{y} \in \mathcal{V},$$
 (7.9)

where  $||x||_{A_t}$  is defined as  $\sqrt{x^\top A_t x}$ . Note that this is a weaker property than strong convexity because  $A_t$  depends on x. On the other hand, in the characterization of strong convexity in Lemma 4.2 we want the last term to be the same norm everywhere in the space. See also Exercise 6.8 for a similar generalization of strong convexity.

The rationale of this new definition is that it still allows us to build surrogate loss functions, but without requiring to have strong convexity over the entire space. In particular, we can think to use FTRL on the surrogate losses

$$ilde{\ell}_t(oldsymbol{x}) = \langle oldsymbol{g}_t, oldsymbol{x} 
angle + rac{1}{2} \|oldsymbol{x}_t - oldsymbol{x}\|_{oldsymbol{A}_t}^2$$

and the regularizers  $\psi_t(x) = \frac{\lambda}{2} ||x||_2^2$ , where  $\lambda > 0$ . Observe that, as in the surrogate losses for the strongly convex case,  $g_t \in \partial \tilde{\ell}_t(x_t)$ . We will denote by  $S_t = \lambda I_d + \sum_{i=1}^t A_i$ .

**Remark 7.27.** Note that  $\|x\|_{S_t} := \sqrt{x \top S_t x}$  is a norm because  $S_t$  is positive definite and  $f(x) = \frac{1}{2} x^\top S_t x$  is 1-strongly convex w.r.t.  $\|\cdot\|_{S_t}$  defined as  $\|x\|_{S_t} = \sqrt{x^\top S_t x}$  (from Theorem 4.3 given that the Hessian is  $S_t$  and  $\boldsymbol{x}^{\top} \nabla^2 f(\boldsymbol{y}) \boldsymbol{x} = \|\boldsymbol{x}\|_{\boldsymbol{S}_t}^2$ ). Also, from Example 4.18, the dual norm of  $\|\cdot\|_{\boldsymbol{S}_t}$  is  $\|\cdot\|_{\boldsymbol{S}_t^{-1}}$ .

From the above remark, we have that the  $\psi_t(x) + \sum_{i=1}^t \tilde{\ell}_t(x)$  is 1-strongly convex w.r.t  $\|\cdot\|_{S_t}$ . Hence, using the FTRL regret equality in Lemma 7.1 and Lemma 7.6, we immediately get the following guarantee

$$\sum_{t=1}^{T} \tilde{\ell}_t(\boldsymbol{x}_t) - \sum_{t=1}^{T} \tilde{\ell}_t(\boldsymbol{u}) = \sum_{t=1}^{T} \left( \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle - \langle \boldsymbol{g}_t, \boldsymbol{u} \rangle - \frac{1}{2} \|\boldsymbol{x}_t - \boldsymbol{u}\|_{A_t}^2 \right)$$

$$\leq \frac{\lambda}{2} \|\boldsymbol{u}\|_2^2 - \min_{\boldsymbol{x} \in \mathcal{V}} \frac{\lambda}{2} \|\boldsymbol{x}\|_2^2 + \frac{1}{2} \sum_{t=1}^{T} \|\boldsymbol{g}_t\|_{\boldsymbol{S}_t^{-1}}^2.$$

So, reordering the terms we have

$$\sum_{t=1}^{T} \ell_{t}(\boldsymbol{x}_{t}) - \sum_{t=1}^{T} \ell_{t}(\boldsymbol{u}) \leq \sum_{t=1}^{T} \left( \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{u} \rangle - \frac{1}{2} \| \boldsymbol{u} - \boldsymbol{x}_{t} \|_{\boldsymbol{A}_{t}}^{2} \right) = \sum_{t=1}^{T} (\tilde{\ell}_{t}(\boldsymbol{x}_{t}) - \tilde{\ell}_{t}(\boldsymbol{u}))$$

$$\leq \frac{\lambda}{2} \| \boldsymbol{u} \|_{2}^{2} - \min_{\boldsymbol{x} \in \mathcal{V}} \frac{\lambda}{2} \| \boldsymbol{x} \|_{2}^{2} + \frac{1}{2} \sum_{t=1}^{T} \| \boldsymbol{g}_{t} \|_{\boldsymbol{S}_{t}^{-1}}^{2}. \tag{7.10}$$

Note how the proof and the algorithm mirror what we did for FTRL with strongly convex losses in Section 7.9.

Remark 7.28. It is possible to generalize Lemma 7.6 to hold in this generalized notion of strong convexity. This would allow to get exactly the same bound running FTRL over the original losses with regularizer  $\psi(\mathbf{x}) = \frac{\lambda}{2} ||\mathbf{x}||_2^2$ .

Let's now see a practical instantiation of this idea. Consider the case that the sequence of loss functions we receive satisfy

$$\ell_t(\boldsymbol{x}) - \ell_t(\boldsymbol{u}) \le \langle \boldsymbol{g}, \boldsymbol{x} - \boldsymbol{u} \rangle - \frac{\mu}{2} (\langle \boldsymbol{g}, \boldsymbol{x} - \boldsymbol{u} \rangle)^2, \ \forall \boldsymbol{x}, \boldsymbol{u} \in \mathcal{V}, \boldsymbol{g} \in \partial \ell_t(\boldsymbol{x}).$$
 (7.11)

In words, we assume to have a class of functions that can be lower bounded by a quadratic that depends on the current subgradient. In particular, these functions guarantee a minimal curvature only in the direction of (any of) their subgradients. Denoting by  $A_t = \mu \boldsymbol{g}_t \boldsymbol{g}_t^{\top}$ , we can use the above idea using

$$ilde{\ell}_t(oldsymbol{x}) = \langle oldsymbol{g}_t, oldsymbol{x} 
angle + rac{1}{2} \|oldsymbol{x}_t - oldsymbol{x}\|_{oldsymbol{A}_t}^2 = \langle oldsymbol{g}_t, oldsymbol{x} 
angle + rac{\mu}{2} (\langle oldsymbol{g}_t, oldsymbol{x} - oldsymbol{x}_t 
angle)^2.$$

Hence, the update rule would be

$$oldsymbol{x}_t = \operatorname*{argmin}_{oldsymbol{x} \in \mathcal{V}} \ rac{\lambda}{2} \|oldsymbol{x}\|_2^2 + \sum_{i=1}^{t-1} \left( \langle oldsymbol{g}_i, oldsymbol{x} 
angle + rac{\mu}{2} (\langle oldsymbol{g}_i, oldsymbol{x} - oldsymbol{x}_i 
angle )^2 
ight) \ .$$

We obtain the following algorithm, called Online Newton Step (ONS).

#### Algorithm 7.6 Online Newton Step Algorithm

**Require:**  $V \subset \mathbb{R}^d$  closed non-empty convex set,  $\lambda, \mu > 0$ 

- 1: for t = 1 to T do
- Set  $m{x}_t = \operatorname{argmin}_{m{x} \in \mathcal{V}} \frac{\lambda}{2} \| m{x} \|_2^2 + \sum_{i=1}^{t-1} \left( \langle m{g}_i, m{x} \rangle + \frac{\mu}{2} (\langle m{g}_i, m{x} m{x}_i \rangle)^2 \right)$  Pay  $\ell_t(m{x}_t)$  for  $\ell_t : \mathcal{V} \to \mathbb{R}$  subdifferentiable in  $\mathcal{V}$
- Set  $\boldsymbol{g}_t \in \partial \ell(\boldsymbol{x}_t)$
- 5: end for

Denoting by  $S_t = \lambda \boldsymbol{I}_d + \sum_{i=1}^t \boldsymbol{A}_i$  and using (7.10), we have

$$\sum_{t=1}^T \ell_t(\boldsymbol{x}_t) - \sum_{t=1}^T \ell_t(\boldsymbol{u}) \leq \frac{\lambda}{2} \|\boldsymbol{u}\|_2^2 - \min_{\boldsymbol{x} \in \mathcal{V}} \frac{\lambda}{2} \|\boldsymbol{x}\|_2^2 + \frac{1}{2} \sum_{t=1}^T \|\boldsymbol{g}_t\|_{\boldsymbol{S}_t^{-1}}^2.$$

To bound the last term, we will use the following Lemma.

**Lemma 7.29.** Let  $\mathbf{g}_1, \dots, \mathbf{z}_T$  an arbitrary sequence of vectors in  $\mathbb{R}^d$  and  $\mu, \lambda > 0$ . Define  $\mathbf{S}_t = \lambda \mathbf{I}_d + \mu \sum_{i=1}^t \mathbf{g}_i \mathbf{g}_i^\top$ . Then, the following holds

$$\sum_{t=1}^T \boldsymbol{g}_t^{\top} \boldsymbol{S}_t^{-1} \boldsymbol{g}_t \leq \frac{1}{\mu} \sum_{i=1}^d \ln \left( 1 + \frac{\mu \lambda_i}{\lambda} \right),$$

where  $\lambda_1, \ldots, \lambda_d$  are the eigenvalues of  $\sum_{i=1}^T \boldsymbol{g}_i \boldsymbol{g}_i^{\top}$ .

*Proof.* First, we will prove the so-called matrix determinant lemma for any invertible  $B \in \mathbb{R}^{d \times d}$ :

$$\det(\boldsymbol{B} + \boldsymbol{u}\boldsymbol{v}^{\top}) = \det(\boldsymbol{B})(1 + \boldsymbol{v}^{\top}\boldsymbol{B}^{-1}\boldsymbol{u}), \ \forall \boldsymbol{u}, \boldsymbol{v} \in \mathbb{R}^{d}.$$

First observe that the matrix  $uv^{\top}$  has one eigenvalue equal to  $v^{\top}u$  and the remaining d-1 are 0. Hence, we have that

$$\det(\boldsymbol{I} + \boldsymbol{u}\boldsymbol{v}^{\top}) = 1 + \boldsymbol{v}^{\top}\boldsymbol{u} .$$

Using this equality, we have

$$\det(\boldsymbol{B} + \boldsymbol{u}\boldsymbol{v}^{\top}) = \det(\boldsymbol{B})\det(\boldsymbol{I} + \boldsymbol{B}^{-1}\boldsymbol{u}\boldsymbol{v}^{\top}) = \det(\boldsymbol{B})(1 + \boldsymbol{v}^{\top}\boldsymbol{B}^{-1}\boldsymbol{u}) \ .$$

Now, setting  $oldsymbol{u} = -\sqrt{\mu} oldsymbol{g}_t, oldsymbol{v} = \sqrt{\mu} oldsymbol{g}_t$  and  $oldsymbol{B} = oldsymbol{S}_t$ , we have

$$\det(\boldsymbol{S}_{t-1}) = \det(\boldsymbol{S}_t - \mu \boldsymbol{g}_t \boldsymbol{g}_t^{\top}) = \det(\boldsymbol{S}_t)(1 - \mu \boldsymbol{g}_t \boldsymbol{S}_t^{-1} \boldsymbol{g}_t).$$

Reordering the terms and summing over t = 1, ..., T, we have

$$\sum_{t=1}^T \boldsymbol{g}_t^\top \boldsymbol{S}_t^{-1} \boldsymbol{g}_t = \frac{1}{\mu} \sum_{t=1}^T \left( 1 - \frac{\det(\boldsymbol{S}_{t-1})}{\det(\boldsymbol{S}_t)} \right) \leq \frac{1}{\mu} \sum_{t=1}^T \ln \frac{\det(\boldsymbol{S}_t)}{\det(\boldsymbol{S}_{t-1})} = \frac{1}{\mu} \ln \frac{\det(\boldsymbol{S}_T)}{\det(\boldsymbol{S}_0)} = \frac{1}{\mu} \sum_{i=1}^d \ln \left( 1 + \frac{\mu \lambda_i}{\lambda} \right),$$

where in the inequality we used the elementary inequality  $1 - x \le \ln 1/x$  for x > 0.

Using this lemma and assuming  $\|g_t\|_2 \le L$  and (7.11) holds for the losses, then ONS satisfies the following regret

$$\sum_{t=1}^{T} \ell_t(\boldsymbol{x}_t) - \sum_{t=1}^{T} \ell_t(\boldsymbol{u}) \leq \frac{\lambda}{2} \|\boldsymbol{u}\|_2^2 - \min_{\boldsymbol{x} \in \mathcal{V}} \frac{\lambda}{2} \|\boldsymbol{x}\|_2^2 + \frac{1}{2\mu} \sum_{i=1}^{d} \ln\left(1 + \frac{\mu\lambda_i}{\lambda}\right)$$
$$\leq \frac{\lambda}{2} \|\boldsymbol{u}\|_2^2 - \min_{\boldsymbol{x} \in \mathcal{V}} \frac{\lambda}{2} \|\boldsymbol{x}\|_2^2 + \frac{d}{2\mu} \ln\left(1 + \frac{\mu T L^2}{d\lambda}\right),$$

where in the second inequality we used the inequality of arithmetic and geometric means,  $(\prod_{i=1}^d x_i)^{1/d} \leq \frac{1}{d} \sum_{i=1}^d x_i$ , and the fact that  $\sum_{i=1}^d \lambda_i \leq TL^2$ .

Hence, if the losses satisfy (7.11), we can guarantee a logarithmic regret. However, differently from the strongly convex case, here the complexity of the update is at least quadratic in the number of dimensions. Moreover, the regret also depends linearly on the number of dimensions.

**Remark 7.30.** Despite the name, the ONS algorithm should not be confused with the Newton algorithm. They are similar in spirit because they both construct quadratic approximation to the function, but the Newton algorithm uses the exact Hessian while the ONS uses an approximation that works only for a restricted class of functions. In this view, the ONS algorithm is more similar to Quasi-Newton methods. However, the best lens to understand the ONS is still through the generalized concept of strong convexity.

Let's now see an example of functions that satisfy (7.11).

**Example 7.31** (Exp-Concave Losses). *Defining*  $X \subseteq \mathbb{R}^d$  *convex, we say that a function*  $f: X \to \mathbb{R}$  *is*  $\alpha$ *-exp-concave* if  $\exp(-\alpha f(\boldsymbol{x}))$  is concave.

Choose  $\beta \leq \frac{\alpha}{2}$  such that  $|\beta(\mathbf{g}, \mathbf{y} - \mathbf{x})| \leq \frac{1}{2}$  for all  $\mathbf{x}, \mathbf{y} \in \mathcal{X}$  and  $\mathbf{g} \in \partial f(\mathbf{x})$ . For  $\beta$  to exist, we need  $\mathcal{X}$  to be a bounded domain. Then, this class of functions satisfy the property (7.11). In fact, given that f is  $\alpha$ -exp-concave then it is also  $2\beta$ -exp-concave. Hence, from the definition we have

$$\exp(-2\beta f(\mathbf{y})) \le \exp(-2\beta f(\mathbf{x})) - 2\beta \exp(-2\beta f(\mathbf{x})) \langle \mathbf{g}, \mathbf{y} - \mathbf{x} \rangle,$$

that is

$$\exp(-2\beta f(\mathbf{y}) + 2\beta f(\mathbf{x})) < 1 - 2\beta \langle \mathbf{g}, \mathbf{y} - \mathbf{x} \rangle,$$

that implies

$$f(\boldsymbol{x}) - f(\boldsymbol{y}) \le \frac{1}{2\beta} \ln \left( 1 + 2\beta \langle \boldsymbol{g}, \boldsymbol{x} - \boldsymbol{y} \rangle \right) \le \langle \boldsymbol{g}, \boldsymbol{x} - \boldsymbol{y} \rangle - \frac{\beta}{2} (\langle \boldsymbol{g}, \boldsymbol{y} - \boldsymbol{x} \rangle)^2,$$

where we used the elementary inequality  $\ln(1+x) \le x - x^2/4$ , for  $|x| \le 1$ .

For example, assuming the losses to be  $\alpha$ -exp-concave, the L2 diameter of the feasible set V to be bounded by D, and the L2 norm of the subgradient to be bounded by G, we can set  $\beta = \frac{1}{2} \min(\frac{1}{GD}, \alpha)$ .

**Example 7.32.** Let  $V = \{ \boldsymbol{x} \in \mathbb{R}^d : \|\boldsymbol{x}\|_2 \leq U \}$ . The logistic loss of a linear predictor  $\ell(\boldsymbol{x}) = \ln(1 + \exp(-\langle \boldsymbol{z}, \boldsymbol{x} \rangle))$ , where  $\|\mathbf{z}\|_2 \leq 1$  is  $\exp(-2U)/2$ -exp-concave.

Remark 7.33. Using the online-to-batch conversion in Theorem 3.1, the above theorem says that we can minimize stochastic exp-concave losses with a convergence rate in expectation of  $\mathcal{O}(\frac{d \ln T}{T})$ . Hence, up to logarithmic terms, we obtain a  $\mathcal{O}(1/T)$  convergence rate without strong convexity.

#### 7.11 Online Linear Regression: Vovk-Azoury-Warmuth Forecaster

Let's now consider the specific case that  $\ell_t(x) = \frac{1}{2}(\langle z_t, x \rangle - y_t)^2$  and  $\mathcal{V} = \mathbb{R}^d$ , that is the one of *unconstrained* online linear regression with square loss. These losses are not strongly convex w.r.t. x, but they are exp-concave when the domain is bounded. We could use the ONS algorithm, but it would not work in the unbounded case. Another possibility would be to run FTRL, but that losses are not strongly convex and we would get only a  $\mathcal{O}(\sqrt{T})$  regret.

It turns out we can still get a logarithmic regret, if we make an additional assumption. We will assume to have access to  $z_t$  before predicting  $x_t$ . Note that this is a mild assumptions in many interesting applications in machine learning. Then, we will use the same strategy we used for the composite losses in Section 7.8, that is we put in the regularizer the future part of the loss we know we will receive, that is  $\frac{1}{2}(\langle z_t, x \rangle)^2$ . This has also another equivalent interpretation as running FTRL over the past losses plus the loss on the received  $z_t$  hallucinating a label of 0. We will call this algorithm Vovk-Azoury-Warmuth forecaster, from the names of the inventors. The details are in Algorithm 7.7.

#### Algorithm 7.7 Vovk-Azoury-Warmuth Forecaster

```
Require: \lambda > 0
```

- 1: for t = 1 to T do
- Receive  $\boldsymbol{z}_t \in \mathbb{R}^d$
- Set  $x_t = \underset{\boldsymbol{x}}{\operatorname{argmin}}_{\boldsymbol{x}} \frac{\lambda}{2} \|\boldsymbol{x}\|_2^2 + \frac{1}{2} \sum_{i=1}^{t-1} (\langle \boldsymbol{z}_i, \boldsymbol{x} \rangle y_i)^2 + \frac{1}{2} (\langle \boldsymbol{z}_t, \boldsymbol{x} \rangle)^2$ Receive  $y_t \in \mathbb{R}$  and pay  $\ell(\boldsymbol{x}_t) = \frac{1}{2} (\langle \boldsymbol{z}_t, \boldsymbol{x}_t \rangle y_t)^2$

As we did for composite losses, we look closely to the loss functions, to see if there are terms that we might move inside the regularizer. The motivation would be the same as in the composite losses case: the bound will depend only on the subgradients of the part of the losses that are outside of the regularizer.

So, observe that

$$\ell_t(\boldsymbol{x}) = \frac{1}{2} (\langle \boldsymbol{z}_t, \boldsymbol{x} \rangle)^2 - y_t \langle \boldsymbol{z}_t, \boldsymbol{x} \rangle + \frac{1}{2} y_t^2.$$

From the above, we see that we could think to move the terms  $\frac{1}{2}(\langle z_t, x_t \rangle)^2$  in the regularizer and leaving the linear terms in the loss:  $\tilde{\ell}_t(x) = -y_t\langle z_t, x \rangle$ . Hence, we will use

$$\psi_t(oldsymbol{x}) = rac{1}{2} oldsymbol{x}^ op \left( \sum_{i=1}^t oldsymbol{z}_i oldsymbol{z}_i^ op 
ight) oldsymbol{x} + rac{\lambda}{2} \|oldsymbol{x}\|_2^2 \ .$$

Note that the regularizer at time t contains the  $z_t$  that is revealed to the algorithm before it makes its prediction. For simplicity of notation, denote by  $S_t = \lambda \boldsymbol{I}_d + \sum_{i=1}^t \boldsymbol{z}_i \boldsymbol{z}_i^{\top}$ .

Remark 7.34. This splitting of the loss between the regularizer and the surrogate linear losses is important because now the gradient of the surrogate is just  $-y_t z_t$ , that is controlled if  $z_t$  is controlled, instead the gradient of the original losses is  $y_t z_t(\langle z_t, x \rangle - y_t)$  that is not controlled for unbounded domains. However, now Lemma 7.6 will give us a strong convexity that depends on the strong convexity of  $\psi_t$ , and this is exactly the reason why we need  $(\langle z_t, x \rangle)^2$  in the regularizer.

Using such procedure, the prediction can be written in a closed form:

$$\mathbf{x}_t = \underset{\mathbf{x}}{\operatorname{argmin}} \frac{\lambda}{2} \|\mathbf{x}\|_2^2 + \frac{1}{2} \sum_{i=1}^{t-1} (\langle \mathbf{z}_i, \mathbf{x} \rangle - y_i)^2 + \frac{1}{2} (\langle \mathbf{z}_t, \mathbf{x} \rangle)^2$$
$$= \left(\lambda \mathbf{I}_d + \sum_{i=1}^t \mathbf{z}_i \mathbf{z}_i^\top \right)^{-1} \sum_{i=1}^{t-1} y_i \mathbf{z}_i.$$

Using an incremental update of the inverse using the Sherman–Morrison formula, the computational complexity of this update is  $\mathcal{O}(d^2)$ .

Hence, using the regret we proved for FTRL with strongly convex regularizers and  $\psi_{T+1} = \psi_T$ , we get the following guarantee

$$\sum_{t=1}^{T} \left( \tilde{\ell}_{t}(\boldsymbol{x}_{t}) - \tilde{\ell}_{t}(\boldsymbol{u}) \right) = \sum_{t=1}^{T} \left( -y_{t} \langle \boldsymbol{z}_{t}, \boldsymbol{x}_{t} \rangle + y_{t} \langle \boldsymbol{z}_{t}, \boldsymbol{u} \rangle \right) 
\leq \psi_{T}(\boldsymbol{u}) - \min_{\boldsymbol{x}} \ \psi_{T}(\boldsymbol{x}) + \frac{1}{2} \sum_{t=1}^{T} y_{t}^{2} \boldsymbol{z}_{t}^{\top} \boldsymbol{S}_{t}^{-1} \boldsymbol{z}_{t} + \sum_{t=1}^{T-1} \left( \psi_{t}(\boldsymbol{x}_{t+1}) - \psi_{t+1}(\boldsymbol{x}_{t+1}) \right) 
= \frac{1}{2} \boldsymbol{u}^{\top} S_{T} \boldsymbol{u} + \frac{1}{2} \sum_{t=1}^{T} y_{t}^{2} \boldsymbol{z}_{t}^{\top} \boldsymbol{S}_{t}^{-1} \boldsymbol{z}_{t} - \frac{1}{2} \sum_{t=1}^{T-1} \left( \langle \boldsymbol{z}_{t+1}, \boldsymbol{x}_{t+1} \rangle \right)^{2}.$$

Noting that  $x_1 = 0$  and reordering the terms, we have

$$\begin{split} \sum_{t=1}^T \frac{1}{2} (\langle \boldsymbol{z}_t, \boldsymbol{x}_t \rangle - y_t)^2 - \sum_{t=1}^T \frac{1}{2} (\langle \boldsymbol{z}_t, \boldsymbol{u} \rangle - y_t)^2 &= \frac{1}{2} \sum_{t=1}^T (\langle \boldsymbol{z}_t, \boldsymbol{x}_t \rangle)^2 + \sum_{t=1}^T (-y_t \langle \boldsymbol{z}_t, \boldsymbol{x}_t \rangle + y_t \langle \boldsymbol{z}_t, \boldsymbol{u} \rangle) - \frac{1}{2} \sum_{t=1}^T (\langle \boldsymbol{z}_t, \boldsymbol{u} \rangle)^2 \\ &\leq \frac{\lambda}{2} \|\boldsymbol{u}\|_2^2 + \frac{1}{2} \sum_{t=1}^T y_t^2 \boldsymbol{z}_t^\top \boldsymbol{S}_t^{-1} \boldsymbol{z}_t \;. \end{split}$$

Remark 7.35. Note that, differently from the ONS algorithm, the strong convexity comes from the regularizer. Yet, the bound depends on  $S_t^{-1}$  instead of  $S_{t-1}^{-1}$  because the current sample  $z_t$  is used in the regularizer. Without the knowledge of  $z_t$  the last term would be  $\frac{1}{2} \sum_{t=1}^{T} y_t^2 z_t^{\top} S_{t-1}^{-1} z_t$  that would have to be controlled using  $\lambda$  and a bound on the norms of  $z_t$ .

So, using again Lemma 7.29 and assuming  $|y_t| \leq Y$ ,  $t = 1, \dots, T$ , we have

$$\sum_{t=1}^T \frac{1}{2} (\langle \boldsymbol{z}_t, \boldsymbol{x}_t \rangle - y_t)^2 - \sum_{t=1}^T \frac{1}{2} \sum_{t=1}^T (\langle \boldsymbol{z}_t, \boldsymbol{u} \rangle - y_t)^2 \leq \frac{\lambda}{2} \|\boldsymbol{u}\|_2^2 + \frac{Y^2}{2} \sum_{i=1}^d \ln \left( 1 + \frac{\lambda_i}{\lambda} \right),$$

where  $\lambda_1, \dots, \lambda_d$  are the eigenvalues of  $\sum_{i=1}^T z_i z_i^{\top}$ .

If we assume that  $\|z_t\|_2 \le R$ , we can reason as we did for the similar term in ONS, to have

$$\sum_{i=1}^{d} \ln \left( 1 + \frac{\lambda_i}{\lambda} \right) \le d \ln \left( 1 + \frac{R^2 T}{\lambda d} \right) .$$

Putting all together, we have the following theorem.

**Theorem 7.36.** Assume  $||z_t||_2 \le R$  and  $|y_t| \le Y$  for t = 1, ..., T. Then, using the prediction strategy in Algorithm 7.7, we have

$$\sum_{t=1}^{T} \frac{1}{2} (\langle \boldsymbol{z}_t, \boldsymbol{x}_t \rangle - y_t)^2 - \sum_{t=1}^{T} \frac{1}{2} (\langle \boldsymbol{z}_t, \boldsymbol{u} \rangle - y_t)^2 \leq \frac{\lambda}{2} \|\boldsymbol{u}\|_2^2 + \frac{dY^2}{2} \ln \left( 1 + \frac{R^2T}{\lambda d} \right), \ \forall \boldsymbol{u} \in \mathbb{R}^d.$$

**Remark 7.37.** It is possible to show that the regret of the Vovk-Azoury-Warmuth forecaster is optimal up to multiplicative factors [Cesa-Bianchi and Lugosi, 2006, Theorem 11.9].

**Remark 7.38.** We say that an online learning algorithm is improper if the prediction strategy can be chosen from a larger class than the competitor one. So, the Vovk-Azoury-Warmuth forecaster is improper because we measure its regret with respect to a linear predictor u, but the Vovk-Azoury-Warmuth prediction depends in a non-linear way by  $z_t$ .

### 7.12 Optimistic FTRL

In Section 6.9, we have seen that it is possible to achieve better regret guarantees through the so-called Optimistic OMD, that uses a prediction of the next gradient. Here, we will extend the same idea to FTRL, where we predict the next loss function. If our predicted loss is correct, we can expect the regret to decrease. However, if our prediction is wrong we still want to recover the worst case guarantee. Such algorithm is called **Optimistic FTRL**, see Algorithm 7.8. As in Optimistic OMD, we do not make any assumption on how the prediction of the next loss is generated.

#### Algorithm 7.8 Optimistic Follow-the-Regularized-Leader Algorithm

**Require:** A sequence of regularizers  $\psi_1, \dots, \psi_T : \mathcal{X} \to \mathbb{R}$ , closed non-empty convex set  $\mathcal{V} \subseteq \mathcal{X} \subseteq \mathbb{R}^d$ 

- 1: for t = 1 to T do
- 2: Predict next loss  $\ell_t: V \to \mathbb{R}$
- 3: Output  $x_t \in \operatorname{argmin}_{x \in \mathcal{V}} \psi_t(x) + \tilde{\ell}_t(x) + \sum_{i=1}^{t-1} \ell_i(x)$
- 4: Receive  $\ell_t: \mathcal{V} \to \mathbb{R}$  and pay  $\ell_t(\boldsymbol{x}_t)$
- 5: end for

Let's see why this is a good idea. Remember that FTRL simply predicts with the minimizer of the previous losses plus a time-varying regularizer. Let's assume for a moment that instead we have the gift of predicting the future, so we do know the next loss ahead of time. Then, we could predict with its minimizer and suffer a negative regret. However, probably our foresight abilities are not so powerful, so our prediction of the next loss might be inaccurate. In this case, a better idea might be just to add our predicted loss to the previous ones and minimize the regularized sum. We would expect the regret guarantee to improve if our prediction of the future loss is precise. At the same time, if the prediction is wrong, we expect its influence to be limited, given that we use it together with all the past losses.

All these intuitions can be formalized in the following Theorem.

**Theorem 7.39.** With the notation in Algorithm 7.8, let  $\mathcal{V}$  be convex, closed, non-empty. Denote by  $F_t(\mathbf{x}) = \psi_t(\mathbf{x}) + \sum_{i=1}^{t-1} \ell_i(\mathbf{x})$ . For  $t = 1, \ldots, T$ , if  $F_t$  is closed, subdifferentiable, and strongly convex in  $\mathcal{V}$ , then  $\mathbf{x}_t$  exists and is unique. In addition, for  $t = 1, \ldots, T$ , assume  $\partial(\ell_t - \tilde{\ell}_t)(\mathbf{x}_t)$  to be non-empty and  $F_t + \ell_t$  to be closed, subdifferentiable, and  $\lambda_t$ -strongly convex w.r.t.  $\|\cdot\|$  in  $\mathcal{V}$ . Then, we have

$$\begin{split} & \sum_{t=1}^{T} \ell(\boldsymbol{x}_{t}) - \sum_{t=1}^{T} \ell_{t}(\boldsymbol{u}) \\ & \leq \psi_{T+1}(\boldsymbol{u}) - \psi_{1}(\boldsymbol{x}_{1}) + \sum_{t=1}^{T} \left[ \langle \hat{\boldsymbol{g}}_{t}, \boldsymbol{x}_{t} - \boldsymbol{x}_{t+1} \rangle - \frac{\lambda_{t}}{2} \|\boldsymbol{x}_{t} - \boldsymbol{x}_{t+1}\|^{2} + \psi_{t}(\boldsymbol{x}_{t+1}) - \psi_{t+1}(\boldsymbol{x}_{t+1}) \right] \\ & \leq \psi_{T+1}(\boldsymbol{u}) - \psi_{1}(\boldsymbol{x}_{1}) + \sum_{t=1}^{T} \left[ \frac{\|\hat{\boldsymbol{g}}_{t}\|_{\star}^{2}}{2\lambda_{t}} + \psi_{t}(\boldsymbol{x}_{t+1}) - \psi_{t+1}(\boldsymbol{x}_{t+1}) \right], \end{split}$$

for all  $u \in V$  and all  $\hat{g}_t \in \partial(\ell_t - \tilde{\ell}_t)(x_t)$  for t = 1, ..., T,

*Proof.* We can interpret the Optimistic-FTRL as FTRL with a regularizer  $\tilde{\psi}_t(x) = \psi_t(x) + \tilde{\ell}_t(x)$ . So, as in Lemma 7.6, the existence and unicity of  $x_t$  is given by Theorem 6.9. Also, note that  $\tilde{\ell}_{T+1}(x)$  has no influence on the regret of the algorithm over the T rounds, so we can set it to the null function.

Given that  $u \in \mathcal{V}$ , we can use Lemma 7.1 and discard the last term because non-positive, obtaining

$$\begin{split} \sum_{t=1}^{T} & \ell(\boldsymbol{x}_{t}) - \sum_{t=1}^{T} \ell_{t}(\boldsymbol{u}) \\ & \leq \tilde{\ell}_{T+1}(\boldsymbol{u}) + \psi_{T+1}(\boldsymbol{u}) - \min_{\boldsymbol{x} \in \mathcal{V}} \left(\tilde{\ell}_{1}(\boldsymbol{x}) + \psi_{1}(\boldsymbol{x})\right) + \sum_{t=1}^{T} [F_{t}(\boldsymbol{x}_{t}) - F_{t+1}(\boldsymbol{x}_{t+1}) + \ell_{t}(\boldsymbol{x}_{t}) + \tilde{\ell}_{t}(\boldsymbol{x}_{t}) - \tilde{\ell}_{t+1}(\boldsymbol{x}_{t+1})] \\ & = \psi_{T+1}(\boldsymbol{u}) - \psi_{1}(\boldsymbol{x}_{1}) + \sum_{t=1}^{T} [F_{t}(\boldsymbol{x}_{t}) - F_{t+1}(\boldsymbol{x}_{t+1}) + \ell_{t}(\boldsymbol{x}_{t})], \end{split}$$

where the terms  $\tilde{\ell}_t(\boldsymbol{x}_t) - \tilde{\ell}_{t+1}(\boldsymbol{x}_{t+1})$  form a telescopic sum. Now focus on the terms  $F_t(\boldsymbol{x}_t) - F_{t+1}(\boldsymbol{x}_{t+1}) + \ell_t(\boldsymbol{x}_t)$ . Observe that  $F_t(\boldsymbol{x}) + \ell_t(\boldsymbol{x}) + i_{\mathcal{V}}(\boldsymbol{x})$  is  $\lambda_t$ -strongly convex w.r.t.  $\|\cdot\|$ , hence from Lemma 4.2 we have

$$F_{t}(\boldsymbol{x}_{t}) - F_{t+1}(\boldsymbol{x}_{t+1}) + \ell_{t}(\boldsymbol{x}_{t}) = (F_{t}(\boldsymbol{x}_{t}) + \ell_{t}(\boldsymbol{x}_{t})) - (F_{t}(\boldsymbol{x}_{t+1}) + \ell_{t}(\boldsymbol{x}_{t+1})) + \psi_{t}(\boldsymbol{x}_{t+1}) - \psi_{t+1}(\boldsymbol{x}_{t+1})$$

$$\leq \langle \hat{\boldsymbol{g}}_{t}, \boldsymbol{x}_{t} - \boldsymbol{x}_{t+1} \rangle - \frac{\lambda_{t}}{2} \|\boldsymbol{x}_{t} - \boldsymbol{x}_{t+1}\|^{2} + \psi_{t}(\boldsymbol{x}_{t+1}) - \psi_{t+1}(\boldsymbol{x}_{t+1}),$$

for all  $\hat{g}_t \in \partial(F_t + \ell_t + i_{\mathcal{V}})(\boldsymbol{x}_t)$ . Observing that  $\boldsymbol{x}_t = \operatorname{argmin}_{\boldsymbol{x} \in \mathcal{V}} F_t(\boldsymbol{x}) + \tilde{\ell}_t(\boldsymbol{x})$ , we have  $\boldsymbol{0} \in \partial(F_t + \tilde{\ell}_t + i_{\mathcal{V}})(\boldsymbol{x}_t)$ . Hence, using Theorem 2.22,  $\partial(\ell_t - \tilde{\ell}_t)(\boldsymbol{x}_t) \subseteq \partial(F_t + \ell_t + i_{\mathcal{V}})(\boldsymbol{x}_t)$ .

For the second inequality, by the definition of dual norms, we have that

$$\langle \hat{m{g}}_t, m{x}_t - m{x}_{t+1} 
angle - rac{\lambda_t}{2} \|m{x}_t - m{x}_{t+1}\|^2 \leq \|\hat{m{g}}_t\|_\star \|m{x}_t - m{x}_{t+1}\| - rac{\lambda_t}{2} \|m{x}_t - m{x}_{t+1}\|^2 \leq rac{1}{2\lambda_t} \|\hat{m{g}}_t\|_\star^2 \,.$$

Let's take a look at the second bound in the theorem. Compared to the similar bound for FTRL, we now have the terms  $\|\hat{g}_t\|_{\star}^2$  instead of the ones  $\|g_t\|_{\star}^2$ . Consider the simple case that  $\tilde{\ell}_t(x) = \langle \tilde{g}_t, x \rangle$ , then the bound depends on  $\|g_t - \tilde{g}_t\|_{\star}^2$ . So, if the prediction of the subgradient of next loss is good, that term can become smaller and possibly even zero! On the other hand, if the predictions are bad, for Lipschitz losses we only lose a constant factor. Overall, in the best case we can gain a lot, in the worst case we do not lose that much.

**Example 7.40.** In the case of linear losses  $\ell_t(x) = \langle g_t, x \rangle$  and strongly convex regularizers, the update of optimistic FTRL becomes

$$oldsymbol{x}_t = 
abla \psi^\star_{\mathcal{V},t} \left( -\tilde{oldsymbol{g}}_t - \sum_{t=1}^{t-1} oldsymbol{g}_i 
ight),$$

where  $\psi_{\mathcal{V},t} = \psi_t + i_{\mathcal{V}}$  and we used the hint  $\tilde{\ell}_t(\boldsymbol{x}) = \langle \tilde{\boldsymbol{g}}_t, \boldsymbol{x} \rangle$ . For example, if  $\psi_t(\boldsymbol{x}) = \frac{\sqrt{t}}{2} \|\boldsymbol{x}\|_2^2$ , we have

$$oldsymbol{x}_t = \Pi_{\mathcal{V}} \left( rac{- ilde{oldsymbol{g}}_t - \sum_{t=1}^{t-1} oldsymbol{g}_i}{\sqrt{t}} 
ight),$$

where  $\Pi_{\mathcal{V}}$  is the projection onto  $\mathcal{V}$ .

Despite the simplicity of the algorithm and its analysis, there are many applications of this principle. Here, we will only describe a couple of them, while in Section 12.5 we describe the applications of optimistic algorithms for saddle point optimization.

### 7.12.1 Regret that Depends on the Variance of the Subgradients

Consider of running Optimistic-FTRL on the linearized losses  $\ell_t(x) = \langle g_t, x \rangle$ . We can gain something out of the Optimistic-FTRL compared to plain FTRL if we are able to predict the next  $g_t$ . A simple possibility is to predict the average of the past values,  $\bar{g}_t = \frac{1}{t-1} \sum_{i=1}^{t-1} g_i$ . Indeed, from the first chapter, we know that such strategy is itself an online learning procedure! In particular, it corresponds to a Follow-The-Leader algorithm on the losses  $\ell_t(x) = \|x - g_t\|_2^2$ . Hence, from the strong convexity of these losses and assuming  $\|g_t\|_2 \le 1$ , we know that

$$\sum_{t=1}^{T} \|\bar{\boldsymbol{g}}_t - \boldsymbol{g}_t\|_2^2 - \sum_{t=1}^{T} \|\boldsymbol{u} - \boldsymbol{g}_t\|_2^2 \le 4(1 + \ln T), \ \forall \boldsymbol{u} \in \mathbb{R}^d.$$

This implies

$$\sum_{t=1}^T \|\bar{\boldsymbol{g}}_t - \boldsymbol{g}_t\|_2^2 \leq 4(1 + \ln T) + \min_{\boldsymbol{u}} \sum_{t=1}^T \|\boldsymbol{u} - \boldsymbol{g}_t\|_2^2 \;.$$

It is immediate to see that the minimizer is  $u = \frac{1}{T} \sum_{t=1}^{T} g_t$ , that results in T times the empirical "variance" of the subgradients, that is the sum of the empirical variances of the coordinates of the subgradients. Plugging it in the Optimistic-FTRL regret, with  $\psi_t = \psi$ , we have

$$\sum_{t=1}^{T} \ell(\boldsymbol{x}_{t}) - \sum_{t=1}^{T} \ell_{t}(\boldsymbol{u}) \leq \psi(\boldsymbol{u}) - \psi(\boldsymbol{x}_{1}) + \frac{4 + 4 \ln T + \min_{\boldsymbol{g}} \sum_{t=1}^{T} \|\boldsymbol{g}_{t} - \boldsymbol{g}\|_{2}^{2}}{2\lambda}.$$

**Remark 7.41.** Instead of using the mean of the past subgradients, we could use any other strategy or even a mix of different strategies. For example, assuming the subgradients bounded, we could use an algorithm to solve the Learning with Expert problem, where each expert is a strategy. Then, we would obtain a bound that depends on the predictions of the best strategy, plus the regret of the expert algorithm.

#### 7.12.2 Online Convex Optimization with Gradual Variations

In this section, we consider the case that the losses we receive have small variations over time. We will show that in this case it is possible to get constant regret in the case that the losses are equal.

In this case, the simple strategy we can use to predict the next subgradient is to use the previous one, that is  $\tilde{\ell}_t(x) = \langle g_{t-1}, x \rangle$  for  $t \geq 2$  and  $\tilde{\ell}_1(x) = 0$ .

**Corollary 7.42.** Under the assumptions of Theorem 7.39, also assume that the losses  $\ell_t$  are m-smooth w.r.t.  $\|\cdot\|$ . Define  $\tilde{\ell}_t(\boldsymbol{x}) = \langle \nabla \ell_{t-1}(\boldsymbol{x}_{t-1}), \boldsymbol{x} \rangle$  for  $t \geq 2$  and  $\tilde{\ell}_1(\boldsymbol{x}) = 0$  for all  $\boldsymbol{x} \in \mathcal{V}$ . Set  $\psi_t(\boldsymbol{x}) = \lambda_t \psi(\boldsymbol{x})$  where  $\psi$  is 1-strongly convex w.r.t.  $\|\cdot\|$  and  $\lambda_t$  satisfies  $\lambda_t \lambda_{t-1} \geq 8M^2$  for  $t = 2, \ldots, T$ . Then,  $\forall \boldsymbol{u} \in \mathcal{V}$ , we have

$$\sum_{t=1}^{T} \ell_t(\boldsymbol{x}_t) - \sum_{t=1}^{T} \ell_t(\boldsymbol{u}) \le \lambda_{T+1} \psi(\boldsymbol{u}) - \lambda_1 \psi(\boldsymbol{x}_1) + \frac{1}{\lambda_1} \|\nabla \ell_1(\boldsymbol{x}_1)\|_{\star}^2 + \sum_{t=2}^{T} \frac{2}{\lambda_t} \|\nabla \ell_t(\boldsymbol{x}_{t-1}) - \nabla \ell_{t-1}(\boldsymbol{x}_{t-1})\|_{\star}^2.$$

In addition, assume that in each round t we can also query the gradient of  $\ell_t$  in  $x_{t-1}$ , fix  $\alpha > 0$ , assume  $\|\nabla \ell_t(x)\|_{\star} \leq L$  for all  $x \in \mathcal{V}$ , and set

$$\lambda_t = \frac{1}{\alpha} \sqrt{\max(8\alpha m^2, 4L^2) + \sum_{i=2}^{t-1} \|\nabla \ell_i(\boldsymbol{x}_{i-1}) - \nabla \ell_{i-1}(\boldsymbol{x}_{i-1})\|_{\star}^2}.$$

Then, we have

$$\begin{split} &\sum_{t=1}^T \ell_t(\boldsymbol{x}_t) - \sum_{t=1}^T \ell_t(\boldsymbol{u}) \\ &\leq \left(\frac{\psi(\boldsymbol{u}) - \min_{\boldsymbol{x}} \psi(\boldsymbol{x})}{\alpha} + 4\alpha\right) \sqrt{\max(8\alpha^2 m^2, 4L^2) + \sum_{t=2}^T \|\nabla \ell_t(\boldsymbol{x}_{t-1}) - \nabla \ell_{t-1}(\boldsymbol{x}_{t-1})\|_{\star}^2 + \frac{\alpha L}{2}} \;. \end{split}$$

*Proof.* From the Optimistic-FTRL bound, we immediately get

$$\sum_{t=1}^{T} \ell_t(\boldsymbol{x}_t) - \sum_{t=1}^{T} \ell_t(\boldsymbol{u}) \leq \lambda_T \psi(\boldsymbol{u}) - \lambda_1 \psi(\boldsymbol{x}_1) + \sum_{t=1}^{T} \left[ \langle \boldsymbol{g}_t - \tilde{\boldsymbol{g}}_t, \boldsymbol{x}_t - \boldsymbol{x}_{t+1} \rangle - \frac{\lambda_t}{2} \|\boldsymbol{x}_t - \boldsymbol{x}_{t+1}\|^2 \right],$$

where  $g_t = \nabla \ell_t(x_t)$ . Now, consider the case that the losses  $\ell_t$  are m-smooth. So, for any  $\beta_t > 0$ , we have

$$\begin{split} \langle \boldsymbol{g}_{t} - \tilde{\boldsymbol{g}}_{t}, \boldsymbol{x}_{t} - \boldsymbol{x}_{t+1} \rangle - \frac{\lambda_{t}}{2} \|\boldsymbol{x}_{t} - \boldsymbol{x}_{t+1}\|^{2} &= \langle \nabla \ell_{t}(\boldsymbol{x}_{t}) - \nabla \ell_{t-1}(\boldsymbol{x}_{t-1}), \boldsymbol{x}_{t} - \boldsymbol{x}_{t+1} \rangle - \frac{\lambda_{t}}{2} \|\boldsymbol{x}_{t} - \boldsymbol{x}_{t+1}\|^{2} \\ &\leq \frac{\beta_{t}}{2} \|\nabla \ell_{t}(\boldsymbol{x}_{t}) - \nabla \ell_{t-1}(\boldsymbol{x}_{t-1})\|_{\star}^{2} + \frac{1}{2\beta_{t}} \|\boldsymbol{x}_{t} - \boldsymbol{x}_{t+1}\|^{2} - \frac{\lambda_{t}}{2} \|\boldsymbol{x}_{t} - \boldsymbol{x}_{t+1}\|^{2} \,. \end{split}$$

Focusing on the first term, for t = 2, ..., T, we have

$$\frac{\beta_{t}}{2} \|\nabla \ell_{t}(\boldsymbol{x}_{t}) - \nabla \ell_{t-1}(\boldsymbol{x}_{t-1})\|_{\star}^{2} = \frac{\beta_{t}}{2} \|\nabla \ell_{t}(\boldsymbol{x}_{t}) - \nabla \ell_{t-1}(\boldsymbol{x}_{t-1}) - \nabla \ell_{t}(\boldsymbol{x}_{t-1}) + \nabla \ell_{t}(\boldsymbol{x}_{t-1})\|_{\star}^{2} \\
\leq \beta_{t} \|\nabla \ell_{t}(\boldsymbol{x}_{t}) - \nabla \ell_{t}(\boldsymbol{x}_{t-1})\|_{\star}^{2} + \beta_{t} \|\nabla \ell_{t}(\boldsymbol{x}_{t-1}) - \nabla \ell_{t-1}(\boldsymbol{x}_{t-1})\|_{\star}^{2} \\
\leq \beta_{t} m^{2} \|\boldsymbol{x}_{t} - \boldsymbol{x}_{t-1}\|^{2} + \beta_{t} \|\nabla \ell_{t}(\boldsymbol{x}_{t-1}) - \nabla \ell_{t-1}(\boldsymbol{x}_{t-1})\|_{\star}^{2}.$$

Choose  $\beta_t = \frac{2}{\lambda_t}$ . We have for  $t = 2, \dots, T$ 

$$\langle \boldsymbol{g}_{t} - \tilde{\boldsymbol{g}}_{t}, \boldsymbol{x}_{t} - \boldsymbol{x}_{t+1} \rangle - \frac{\lambda_{t}}{2} \| \boldsymbol{x}_{t} - \boldsymbol{x}_{t+1} \|^{2}$$

$$\leq \frac{2M^{2}}{\lambda_{t}} \| \boldsymbol{x}_{t} - \boldsymbol{x}_{t-1} \|^{2} + \frac{2}{\lambda_{t}} \| \nabla \ell_{t}(\boldsymbol{x}_{t-1}) - \nabla \ell_{t-1}(\boldsymbol{x}_{t-1}) \|_{\star}^{2} - \frac{\lambda_{t}}{4} \| \boldsymbol{x}_{t} - \boldsymbol{x}_{t+1} \|^{2} .$$

For t=1, using the fact that  $\tilde{\ell}_1$  is the null function, we have

$$\|\langle m{g}_1 - ilde{m{g}}_1, m{x}_1 - m{x}_2 
angle - rac{\lambda_1}{2} \|m{x}_1 - m{x}_2\|^2 \leq rac{1}{\lambda_1} \|
abla \ell_1(m{x}_1)\|_\star^2 - rac{\lambda_1}{4} \|m{x}_1 - m{x}_2\|^2 \ .$$

Now observe the assumption on  $\lambda_t$  implies  $\frac{2M^2}{\lambda_t} \leq \frac{\lambda_{t-1}}{4}$  for  $t=2,\ldots,T$ . So, summing for  $t=1,\ldots,T$ , we have

$$\sum_{t=1}^{T} \left( \langle \boldsymbol{g}_{t} - \tilde{\boldsymbol{g}}_{t}, \boldsymbol{x}_{t} - \boldsymbol{x}_{t+1} \rangle - \frac{\lambda_{t}}{2} \|\boldsymbol{x}_{t} - \boldsymbol{x}_{t+1}\|^{2} \right) \leq \frac{1}{\lambda_{1}} \|\nabla \ell_{1}(\boldsymbol{x}_{1})\|_{\star}^{2} + \sum_{t=2}^{T} \frac{2}{\lambda_{t}} \|\nabla \ell_{t}(\boldsymbol{x}_{t-1}) - \nabla \ell_{t-1}(\boldsymbol{x}_{t-1})\|_{\star}^{2}.$$

Putting all together, we have the first stated bound.

The second one is obtained observing that

$$\sum_{t=2}^{T} \frac{\|\nabla \ell_{t}(\boldsymbol{x}_{t-1}) - \nabla \ell_{t-1}(\boldsymbol{x}_{t-1})\|_{\star}^{2}}{\lambda_{t}} = \alpha \sum_{t=2}^{T} \frac{\|\nabla \ell_{t}(\boldsymbol{x}_{t-1}) - \nabla \ell_{t-1}(\boldsymbol{x}_{t-1})\|_{\star}^{2}}{\sqrt{\max(8\alpha^{2}m^{2}, 4L^{2}) + \sum_{i=2}^{t-1} \|\nabla \ell_{i}(\boldsymbol{x}_{i-1}) - \nabla \ell_{i-1}(\boldsymbol{x}_{i-1})\|_{\star}^{2}}} \\
\leq \alpha \sum_{t=2}^{T} \frac{\|\nabla \ell_{t}(\boldsymbol{x}_{t-1}) - \nabla \ell_{t-1}(\boldsymbol{x}_{t-1})\|_{\star}^{2}}{\sqrt{\sum_{i=2}^{t} \|\nabla \ell_{i}(\boldsymbol{x}_{i-1}) - \nabla \ell_{i-1}(\boldsymbol{x}_{i-1})\|_{\star}^{2}}} \\
\leq 2\alpha \sqrt{\sum_{i=2}^{T} \|\nabla \ell_{i}(\boldsymbol{x}_{i-1}) - \nabla \ell_{i-1}(\boldsymbol{x}_{i-1})\|_{\star}^{2}}. \qquad \Box$$

Note that if the losses are all the same, the regret becomes a constant! This is not surprising, because the prediction of the next loss is a linear approximation of the previous loss. Indeed, looking back at the proof, the key idea is to use the smoothness to argue that, if even the past subgradient was taken in a different point than the current one, it is still a good prediction of the current subgradient.

**Remark 7.43.** Note that the assumption of smoothness is necessary. Indeed, passing always the same function and using the online-to-batch conversion would result in a convergence rate of O(1/T) for a Lipschitz function, that is impossible by the lower bound in offline convex optimization.

### 7.13 History Bits

The Follow-the-Regularized-Leader algorithm has a peculiar story. It was introduced by four different groups roughly around 1999-2006 following four different points of view. The algorithm was officially introduced in Abernethy et al. [2008], Hazan and Kale [2008] where at each step the prediction is computed as the minimizer of a regularization term plus the sum of losses on all past rounds. However, the key ideas were already presented years before. Gordon [1999a,b] appeared to have proposed it for the first time, naming it Maximum a Posteriori with a clear inspiration to Bayesian methods. Also, the analysis in Gordon [1999a,b] is the first one to use concepts from convex analysis. Later, Agarwal and Hazan [2005] proposed to add a regularizer to stabilize the Follow The Leader algorithm [Hannan, 1957] in an algorithm named Smooth Prediction for the specific application of Portfolio Selection. A little bit later, Shai Shalev-Shwartz and Yoram Singer proposed a very general analysis of FTRL using a dual perspective [Shalev-Shwartz and Singer, 2006a,b]. In particular, the PhD thesis of Shai Shalev-Shwartz [Shalev-Shwartz, 2007] contains the most precise dual analysis of FTRL, that also allows multiple dual updates and regularizers with a time-varying weight. However, he called it "online mirror descent" because the name FTRL was only invented later! (I also contributed to the confusion naming a general analysis of FTRL with time-varying regularizer and linear losses "generalized online mirror descent" [Orabona et al., 2015]. So, now I am trying to set the record straight:) The optimization community also knows FTRL, but only with linear losses, and they call it Dual Averaging [Nesterov, 2009]. Note that the paper Nesterov [2009] is actually from 2005<sup>1</sup>, and in the paper Nesterov claims that these ideas are from 2001-2002, but he decided not to publish them for a while because he was convinced that "the importance of black-box approach in Convex Optimization will be irreversibly vanishing, and, finally, this approach will be completely replaced by other ones based on a clever use of problem's structure (interior-point methods, smoothing, etc.)." As Shai Shalev-Shwartz, Nesterov looks at FTRL from the dual point of view but he focuses only on linear losses and only in the offline case.

Nesterov's Dual Averaging was then extended to deal with composite losses by Xiao [2009, 2010] in the stochastic and online learning setting, essentially rediscovering the framework of Shalev-Shwartz, and calling the resulting framework Regularized Dual Averaging. Finally, McMahan [2017] gives the elegant equality result that I presented here (with minor improvements) that holds for general loss functions and regularizers. A similar equality, setting  $u = x_{T+1}$  and specialized only to linear losses, was also proven in Abernethy et al. [2014], essentially matching the inequality in Orabona et al. [2015]. Note that Dual Averaging stems from the dual interpretation of FTRL for linear losses, but Lemma 7.1 underlines the fact that FTRL is actually more general. People used to prove the regret bound for FTRL using the so-called be-the-leader-follow-the-leader lemma (see Lemma 1.2 and Exercise 7.3).

https://papers.ssrn.com/sol3/papers.cfm?abstract\_id=912637

However, the proof is off by a factor of 2 in the case of fixed regularizers [McMahan, 2017]. Moreover, it seems to fail in the case of generic strongly convex increasing regularizers, while it works for the particular case of proximal regularizers McMahan [2017].

Another source of confusion stems from the fact that some people differentiate among a "lazy" and "greedy" version of OMD. Zinkevich [2003] introduced the algorithm "lazy projection", that now we know being FTRL with linearized losses in the special case of  $\psi_t(x) = \frac{\eta}{2} ||x||_2^2$ . More generally, as proved in McMahan [2017], what people call the lazy version of OMD is just FTRL with linearized losses and the greedy one is just OMD.

The concept of generalized Bregman divergence has been rediscovered many times in the literature, with different names too. It was first introduced it as the canonical divergence of dually flat spaces in information geometry in Amari [1985, Eq. 3.21]. Independently, it was proposed in (online) optimization by Gordon [1999a,b] to analyze FTRL for fixed regularizers. The equality in Remark 7.12 might be new, but immediate from the regret equality of FTRL.

The second result in Lemma 7.16 is a distillation of the reasoning used in Zimmert and Seldin [2021], but without using duality concepts.

The use of FTRL with the regularizer in (7.5) was proposed in Orabona and Pál [2015, 2018], while here I presented a simpler version of their proof that does not require Fenchel conjugates. The AdaHedge algorithm was introduced in van Erven et al. [2011] and refined in de Rooij et al. [2014]. The analysis reported here is from Orabona and Pál [2015, 2018], that generalized AdaHedge to arbitrary regularizers in AdaFTRL. Additional properties of AdaHedge for the stochastic case were proven in de Rooij et al. [2014].

The first implicit use of the (2,1) group norm I could find is in Bakin [1999], where it is used as a constraint in the first proposed formulation of Group Lasso. However, there is no mention of the fact that this constraint is a norm. Ding et al. [2006] propose the use of the (2,1) group norm for Principal Component Analysis, calling it  $R_1$  norm. Few months later, the same group norm was proposed independently in Argyriou et al. [2006]. Agarwal et al. [2008] extended the (2,1) group norm to (p,s) and used it in OMD for multitask online learning. Kakade et al. [2009] proved the smoothness and strong convexity of squared group norms. Jie et al. [2010] used the (2,s) group norm FTRL for online multi-kernel learning, while Orabona et al. [2010, 2012b] used the same norm in a Perceptron-like algorithm.

The first analysis of FTRL with composite losses is in Xiao [2009, 2010]. The analysis presented here using the negative terms  $\psi_t(x_{t+1}) - \psi_{t+1}(x_{t+1})$  to easily prove regret bounds for FTRL for composite losses is from Orabona et al. [2015].

The first proof of FTRL for strongly convex losses was in Shalev-Shwartz and Singer [2007] (even if they do not call it FTRL). In the same paper, they also define strong convexity with respect to Bregman divergences, rather than just norms, and prove the same logarithmic regret bound (see Exercise 6.8). Analogously, people later defined the concept of smoothness with respect to a Bregman divergence [Birnbaum et al., 2010, 2011], rediscovered in Bauschke et al. [2017]. Later, both concepts were rebranded as "relative smoothness" and "relative strong convexity" [Lu et al., 2018].

FTRL-Proximal was proposed in McMahan and Streeter [2010] for AdaGrad and then further analyzed in McMahan [2011]. There is an interesting bit about FTRL-Proximal: It became very famous in internet companies when Google disclosed in a very influential paper that they were using FTRL-Proximal to train the classifier for click prediction [McMahan et al., 2013]. This generated even more confusion because many people started conflating the term FTRL-Proximal (a specific algorithm) with FTRL (an entire family of algorithms).

The Online Newton Step algorithm was introduced in Hazan et al. [2006, 2007] and it is described to the particular case that the loss functions are exp-concave. The assumption in (7.9) with a fixed matrix A for all points  $\boldsymbol{x}$  is called A-restricted strong convexity in Ryu and Boyd [2014] and it was used for the first time in an online learning algorithm in this book. Exp-concave functions were studied in Kivinen and Warmuth [1999]. Here, I described a slight generalization for any sequence of functions that satisfy (7.11), that in my view better shows the parallel between FTRL over strongly convex functions and ONS. Note that Hazan et al. [2006, 2007] also describes a variant of ONS based on OMD, but I find its analysis less interesting from a didactic point of view. Lemma 7.29 dates back to Lai and Wei [1982, Lemma 2]. Orabona et al. [2012a] obtained a logarithmic  $L^*$  bound, i.e., proportional to  $\ln(1 + \sum_{t=1}^T \ell_t(\boldsymbol{u}))$ , for exp-concave and smooth losses using ONS.

The Vovk-Azoury-Warmuth forecaster was introduced independently by Azoury and Warmuth [2001] and Vovk [2001], and its interpretation as hallucinating the future loss is by Azoury and Warmuth [2001]. The proof presented here is from Orabona et al. [2015].

The Optimistic FTRL version was proposed in Rakhlin and Sridharan [2013b] but analyzed only with fixed self-

concordant regularizers. Steinhardt and Liang [2014] proposed Optimistic FTRL as we know it, even if it was called "Optimistic Mirror Descent" for the misnaming problem I have explained above. Due to the misnaming, Mohri and Yang [2016] appeared to have rediscovered Optimistic FTRL with non-self-concordant regularizers. The proof of Theorem 7.39 I present here is new. A better bound that shows the robustness of Optimistic FTRL to "bad" hints was proven in Flaspohler et al. [2021], that (implicitly) uses the degree of freedom of the FTRL proof underlined in Remark 7.5.

Corollary 7.42 was proved by Chiang et al. [2012] for Optimistic OMD and presented in a similar form for Optimistic FTRL in Joulani et al. [2017], but only for bounded domains.

### 7.14 Exercises

**Problem 7.1.** Prove that the update of FTRL with linearized loss in Example 7.13 is correct.

**Problem 7.2.** Consider FTRL with linearized losses with regularizers  $\psi_t(\mathbf{x})$ . The regret equality in Lemma 7.1 has a term equal to  $F_{T+1}(\mathbf{x}_{T+1}) - F_{T+1}(\mathbf{u})$ . Assume that  $\mathcal{V}$  is convex and non-empty, and  $\psi_{T+1}$  is strictly convex and differentiable in  $\mathbf{x}_{T+1}$ . Then, show that  $F_{T+1}(\mathbf{x}_{T+1}) - F_{T+1}(\mathbf{u}) \leq -B_{\psi_{T+1}}(\mathbf{u}; \mathbf{x}_{T+1})$  for any  $\mathbf{u} \in \mathcal{V}$ .

**Problem 7.3.** Consider FTRL with losses  $\ell_t(\mathbf{x})$  and regularizers  $\psi_t(\mathbf{x})$ . Assume that  $\psi_{t+1} \geq \psi_t$  for  $t = 1, \dots, T-1$ . Denote by  $F_t(\mathbf{x}) := \psi_t(\mathbf{x}) + \sum_{i=1}^{t-1} \ell_t(\mathbf{x})$  and show that

$$F_t(\mathbf{x}_t) - F_{t+1}(\mathbf{x}_{t+1}) + \ell_t(\mathbf{x}_t) \le \ell_t(\mathbf{x}_t) - \ell_t(\mathbf{x}_{t+1})$$
.

**Problem 7.4.** We can obtain  $L^*$  bounds for smooth losses with linearized FTRL with the additional assumption that the losses are Lipschitz, even without knowing the Lipschitz constant. In particular, show that under these assumptions the regularizers  $\psi_t(x) = \frac{\lambda_t}{2} \|x\|_2^2$ , where  $\lambda_t = \sqrt{a + \sum_{i=1}^{t-1} \|g_i\|_2^2}$  and a > 0, would give an  $L^*$  bound. Hint: Use Gaillard et al. [2014, Lemma 14].

**Problem 7.5.** Define  $\lambda_t = a + \sum_{i=1}^{t-1} \frac{b_i}{\lambda_i}$ , where a > 0. Let  $b_t \in [0, m]$  and prove that  $\sum_{t=1}^{T} \frac{b_t}{\lambda_t} \leq \sqrt{2 \sum_{t=1}^{T} b_t} + \frac{m}{a}$ . Use this inequality to design an alternative regularizer that solves the previous exercise. Hint: see Sachs et al. [2022, Proof of Theorem 5].

**Problem 7.6.** Let  $V = \mathbb{R}^d$  and prove that the update in (7.8) is equivalent to the one of OSD with learning rate  $\eta_t = \frac{1}{\sum_{i=1}^t \mu_i}$ , when both algorithms start with  $\mathbf{x}_1 = 0$ .

**Problem 7.7.** Prove the statement in Example 7.32.

**Problem 7.8.** Design and analyze the FTRL version of OMD with p-norms in Section 6.7.

**Problem 7.9.** Consider the learning with expert setting and assume  $\mathbf{g}_{t,i} \in [0,1]$  for all  $t=1,\ldots,d$ . From the analysis of EG with local norms, see (7.4), derive a time-varying regularizer that gives a regret upper bound proportional to  $\ln d + \sqrt{L^*(\mathbf{u}) \ln d}$ , where  $L^*(\mathbf{u}) = \sum_{t=1}^T \langle \mathbf{g}_t, \mathbf{u} \rangle$  for any  $\mathbf{u} \in \Delta^{d-1}$ .

**Problem 7.10.** Prove a regret bound for optimistic FTRL with proximal regularizers.

**Problem 7.11.** Prove that the losses  $\ell_t(x) = \frac{1}{2}(\langle z_t, x \rangle - y_t)^2$ , where  $||z_t||_2 \le 1$ ,  $|y_t| \le 1$ , and  $\mathcal{V} = \{x \in \mathbb{R}^d : ||x||_2 \le 1\}$ , are exp-concave and find the exp-concavity constant.

**Problem 7.12.** Prove that ONS update is equivalent to the following two steps:

$$\tilde{\boldsymbol{x}}_t = S_{t-1}^{-1} \left( \sum_{i=1}^{t-1} A_i \boldsymbol{x}_i - \sum_{i=1}^{t-1} \boldsymbol{g}_i \right)$$
 $\boldsymbol{x}_t = \underset{\boldsymbol{x} \in \mathcal{V}}{\operatorname{argmin}} \|\boldsymbol{x} - \tilde{\boldsymbol{x}}_t\|_{S_{t-1}},$ 

where  $A_t = \sum_{i=1}^t \mathbf{g}_i \mathbf{g}_i^{\top}$  and  $S_t = \lambda I + A_t$ .

**Problem 7.13.** Consider the online learning algorithm for linear regression with square loss that predicts in each round with

$$oldsymbol{x}_t = \mathop{\mathrm{argmin}}_{oldsymbol{x}} \ \lambda \|oldsymbol{x}\|_2^2 + \sum_{i=1}^{t-1} (\langle oldsymbol{z}_i, oldsymbol{x} 
angle - y_i)^2 \ .$$

Prove for it the equality

$$\sum_{t=1}^{T} \frac{(\langle \boldsymbol{z}_{t}, \boldsymbol{x}_{t} \rangle - y_{t})^{2}}{1 + d_{t}} = \min_{\boldsymbol{u}} \ \lambda \|\boldsymbol{u}\|_{2}^{2} + \sum_{i=1}^{t-1} (\langle \boldsymbol{z}_{i}, \boldsymbol{u} \rangle - y_{i})^{2},$$

where  $d_t = \boldsymbol{x}_t^{\top} (\sum_{i=1}^{t-1} \boldsymbol{x}_i \boldsymbol{x}_i^{\top} + \lambda \boldsymbol{I})^{-1} \boldsymbol{x}$ . Hint: see Zhdanov and Kalnishkan [2010, 2013].

**Problem 7.14.** In Section 7.12.1, we showed that it is possible to have a regret bound that depends on the sum of the empirical variances of the coordinates of the subgradients, using the average of the past subgradients as prediction of the next losses. Prove that a similar bound is possible simply using the previous subgradients as predictions of the next losses, i.e.,  $\tilde{\mathbf{g}}_t = \mathbf{g}_{t-1}$ .

## **Chapter 8**

## **Online Linear Classification**

In this chapter, we will consider the problem of online linear classification. We consider the following setting:

- At each time step we receive a sample  $z_t$
- We output a prediction of the binary label  $y_t \in \{-1, 1\}$  of  $z_t$
- We receive the true label and we see if we did a mistake or not
- We update our online classifier

The aim of the online algorithm is to minimize the number of mistakes it does compared to some best fixed classifier. We will focus on linear classifiers, that predicts with the sign of the inner product between a vector  $x_t$  and the input features  $z_t$ . Hence,  $\tilde{y}_t = \text{sign}(\langle z_t, x_t \rangle)$ . This problem can be written again as a regret minimization problem:

$$\operatorname{Regret}_{T}(\boldsymbol{u}) = \sum_{t=1}^{T} \ell_{t}(\boldsymbol{x}_{t}) - \sum_{t=1}^{T} \ell_{t}(\boldsymbol{u}),$$

where  $\ell_t(x) = \mathbf{1}[\operatorname{sign}(\langle z_t, x \rangle) \neq y_t]$ . It should be clear that these losses are non-convex. Hence, we need an alternative way to deal with them. In the following, we will see two possible approaches to this problem.

#### 8.1 Online Randomized Classifier

As we did for the Learning with Expert Advice framework, we might think to convexify the losses using randomization. Hence, on each round we can predict a number in  $q_t \in [-1,1]$  and output the label +1 according with probability  $\frac{1+q_t}{2}$  and the label -1 with probability  $\frac{1-q_t}{2}$ . So, define the random variable

$$\tilde{y}(p) = \begin{cases} +1, & \text{with probability } p, \\ -1, & \text{with probability } 1-p \ . \end{cases}$$

Now observe that  $\mathbb{E}[\tilde{y}(\frac{1+q_t}{2}) \neq y_t] = \frac{1}{2}|q_t - y_t|$ . If we consider linear predictors, we can think to have  $q_t = \langle \boldsymbol{z}_t, \boldsymbol{x}_t \rangle$  and similarly for the competitor  $q'_t = \langle \boldsymbol{z}_t, \boldsymbol{u} \rangle$ . Constraining both the algorithm and the competitor to the space of vectors where  $|\langle \boldsymbol{z}_t, \boldsymbol{x} \rangle| \leq 1$  for  $t = 1, \dots, T$ , we can write

$$\mathbb{E}\left[\sum_{t=1}^{T}\mathbf{1}\left[\tilde{y}(\langle \boldsymbol{z}_{t},\boldsymbol{x}_{t}\rangle)\neq y_{t}\right]-\sum_{t=1}^{T}\mathbf{1}\left[\tilde{y}(\langle \boldsymbol{z}_{t},\boldsymbol{u}\rangle)\neq y_{t}\right]\right]=\mathbb{E}\left[\sum_{t=1}^{T}\frac{1}{2}\left|\langle \boldsymbol{z}_{t},\boldsymbol{x}_{t}\rangle-y_{t}\right|-\sum_{t=1}^{T}\frac{1}{2}\left|\langle \boldsymbol{z}_{t},\boldsymbol{u}\rangle-y_{t}\right|\right].$$

Hence, the surrogate convex loss becomes  $\tilde{\ell}_t(\boldsymbol{x}) = \frac{1}{2}|\langle \boldsymbol{z}_t, \boldsymbol{x} \rangle - y_t|$  and the feasible set is any convex set where we have the property  $|\langle \boldsymbol{z}_t, \boldsymbol{x} \rangle| \leq 1$  for  $t = 1, \dots, T$ .

Given that this problem is convex, assuming  $z_t$  to be bounded w.r.t. some norm, we can use almost any of the algorithms we have seen till now, from Online Mirror Descent to Follow-The-Regularized-Leader. All of them would result in  $\mathcal{O}(\sqrt{T})$  regret upper bounds, assuming that  $z_t$  are bounded in some norm. The only caveat is to restrict  $\langle z_t, x_t \rangle$  in [-1, 1]. One way to do it might be to consider assuming  $\|z_t\|_\star \leq R$  and choose the feasible set  $\mathcal{V} = \{x \in \mathbb{R}^d : \|x\| \leq \frac{1}{R}\}$ .

Putting all together, for example, we can have the following strategy using FTRL with regularizers  $\psi_t(x) = \frac{\sqrt{2t}}{4} ||x||_2^2$ .

#### Algorithm 8.1 Randomized Online Linear Classifier through FTRL

```
Require: R > 0 such that \|\boldsymbol{z}_t\|_2 \leq R for t = 1, \dots, T

1: Set \boldsymbol{\theta}_1 = \mathbf{0} \in \mathbb{R}^d

2: for t = 1 to T do

3: \boldsymbol{x}_t = \eta_t \theta_t \min(\frac{1}{R\eta_t \|\theta_t\|_2}, 1)

4: Receive \boldsymbol{z}_t \in \mathbb{R}^d

5: Predict \tilde{y}_t = \begin{cases} 1, & \text{with probability } \frac{\langle \boldsymbol{z}_t, \boldsymbol{x}_t \rangle + 1}{2} \\ -1, & \text{otherwise} \end{cases}

6: Receive y_t and pay \mathbf{1}[y_t \neq \tilde{y}_t]

7: \boldsymbol{\theta}_{t+1} = \boldsymbol{\theta}_t + \frac{1}{2} \mathrm{sign}(\langle \boldsymbol{z}_t, \boldsymbol{x}_t \rangle - y_t) \boldsymbol{z}_t where \mathrm{sign}(0) := 0

8: end for
```

**Theorem 8.1.** Let  $(z_t, y_t)_{t=1}^T$  an arbitrary sequence of samples/labels couples where  $(z_t, y_t) \in \mathcal{X} \times \{-1, 1\}$  and  $X \subset \mathbb{R}^d$ . Assume  $\|z_t\|_2 \leq R$ , for  $t = 1, \ldots, T$ . Then, running the Randomized Online Linear Classifier algorithm with  $\eta_t = \frac{\sqrt{2}}{\sqrt{t}}$  where  $\alpha > 0$ , for any  $u \in \{x \in \mathbb{R}^d : \|x\|_2 \leq \frac{1}{R}\}$  we have the following guarantee

$$\mathbb{E}\left[\sum_{t=1}^{T}\mathbf{1}[\tilde{y}(\langle \boldsymbol{z}_t, \boldsymbol{x}_t \rangle) \neq y_t]\right] - \mathbb{E}\left[\sum_{t=1}^{T}\mathbf{1}[\tilde{y}(\langle \boldsymbol{z}_t, \boldsymbol{u} \rangle) \neq y_t]\right] \leq \sqrt{2T}.$$

*Proof.* The proof is straightforward from the FTRL regret bound with the chosen increasing regularizer.  $\Box$ 

### 8.2 The Perceptron Algorithm

The above strategy has the shortcoming of restricting the feasible vectors in a possibly very small set. In turn, this could make the performance of the competitor low. In turn, the performance of the online algorithm is only close to the one of the competitor.

Another way to deal with the non-convexity is to compare the number of mistakes that the algorithm does with a convex cumulative loss of the competitor. That is, we can try to prove a weaker regret guarantee:

$$\sum_{t=1}^{T} \mathbf{1}[y_t \neq \tilde{y}_t] - \sum_{t=1}^{T} \ell(\langle \boldsymbol{z}_t, \boldsymbol{u} \rangle, y_t) = \mathcal{O}\left(\sqrt{T}\right). \tag{8.1}$$

In particular, the convex loss we consider is *powers* of the **Hinge Loss**:  $\ell_q(\tilde{y}, y) = \max(1 - \tilde{y}y, 0)^q$ . The hinge loss is a convex upper bound to the 0/1 loss and it achieves the value of zero when the sign of the prediction is correct *and* the magnitude of the inner product is big enough. Moreover, taking powers of it, we get a family of functions that trade-offs the loss for the wrongly classified samples with the one for the correctly classified samples but with a value of  $|\langle z_t, x \rangle| < 1$ , see Figure 8.1.

The oldest algorithm we have to minimize the modified regret in (8.1) is the **Perceptron** algorithm, in Algorithm 8.2. The Perceptron algorithm updates the current prediction  $x_t$  moving in the direction of the current sample multiplied by its label. Let's see why this is a good idea. Assume that  $y_t = 1$  and the algorithm made a mistake. Then, the updated prediction  $x_{t+1}$  would predict a more positive number on the same sample  $z_t$ . In fact, we have

$$\langle \boldsymbol{z}_t, \boldsymbol{x}_{t+1} \rangle = \langle \boldsymbol{z}_t, \boldsymbol{x}_t + y_t \boldsymbol{z}_t \rangle = \langle \boldsymbol{z}_t, \boldsymbol{x}_t \rangle + \|\boldsymbol{z}_t\|_2^2.$$

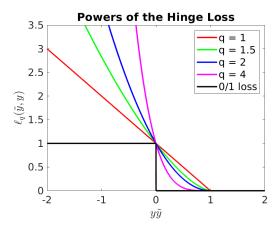

Figure 8.1: Powers of the Hinge Loss.

#### Algorithm 8.2 Perceptron Algorithm

```
1: Set \boldsymbol{x}_1 = \boldsymbol{0} \in \mathbb{R}^d
```

- 2: for t = 1 to T do
- 3: Receive  $\boldsymbol{z}_t \in \mathbb{R}^d$
- 4: Predict  $\tilde{y}_t = \operatorname{sign}(\langle \boldsymbol{z}_t, \boldsymbol{x}_t \rangle)$
- 5: Receive  $y_t$  and pay  $\mathbf{1}[y_t \tilde{y}_t > 0]$
- 6:  $x_{t+1} = x_t + \mathbf{1}[y_t \tilde{y}_t > 0]y_t z_t$
- 7: end for

In the same way, if  $y_t = -1$  and the algorithm made a mistake, the update would result in a more negative prediction on the same sample.

We can formalize the above intuition in the following guarantee.

**Theorem 8.2.** Let  $(z_t, y_t)_{t=1}^T$  an arbitrary sequence of samples/labels couples where  $(z_t, y_t) \in \mathcal{X} \times \{-1, 1\}$  and  $X \subset \mathbb{R}^d$ . Assume  $||z_t||_2 \leq R$ , for  $t = 1, \ldots, T$ . Then, running the Perceptron algorithm we have the following guarantee

$$\sum_{t=1}^{T} \mathbf{1}[y_t \tilde{y}_t > 0] - \sum_{t=1}^{T} \ell_q(\langle \boldsymbol{z}_t, \boldsymbol{u} \rangle, y_t) \leq \frac{q^2 R^2 \|\boldsymbol{u}\|_2^2}{2} + qR \|\boldsymbol{u}\|_2 \sqrt{\frac{q^2 R^2 \|\boldsymbol{u}\|_2^2}{4} + \sum_{t=1}^{T} \ell_q(\langle \boldsymbol{z}_t, \boldsymbol{u} \rangle, y_t)}, \ \forall \boldsymbol{u} \in \mathbb{R}^d, q \geq 1.$$

Before proving the theorem, let's take a look to its meaning. If there exists a  $\boldsymbol{u} \in \mathbb{R}^d$  such that  $\sum_{t=1}^T \ell_q(\langle \boldsymbol{z}_t, \boldsymbol{u} \rangle, y_t) = 0$ , then the Perceptron algorithm makes a *finite* number of mistakes upper bounded by  $R^2 \|\boldsymbol{u}\|_2^2$ , by choosing q=1. In case that are many  $\boldsymbol{u}$  that achieves  $\sum_{t=1}^T \ell_q(\langle \boldsymbol{z}_t, \boldsymbol{u} \rangle, y_t) = 0$  we have that the finite number of mistakes is bounded the norm of the smallest  $\boldsymbol{u}$  among them. What is the meaning of this quantity?

Remember that a hyperplane represented by its normal vector u divides the space in two half spaces: one with the points z that give a positive value for the inner product  $\langle z, u \rangle$  and other one where the same inner product is negative. Now, we have that the distance of a sample  $z_t$  from the hyperplane whose normal is u is

$$rac{|\langle oldsymbol{z}_t, oldsymbol{u}
angle|}{\|oldsymbol{u}\|_2}$$
 .

Also, given that we are considering a u that gives cumulative hinge loss zero, we have that that quantity is at least  $\frac{1}{\|u\|_2}$ . So, the norm of the minimal u that has cumulative hinge loss equal to zero is inversely proportional to the minimum distance between the points and the separating hyperplane. This distance is called the **margin** of the

samples  $(z_t, y_t)_{t=1}^T$ . So, if the margin is small, the Perceptron algorithm can do more mistakes than when the margin is big.

If the problem cannot be linearly separable, the Perceptron satisfies a regret of  $\mathcal{O}(\sqrt{L^{\star}})$ , where  $L^{\star}$  is the cumulative loss of the competitor. Moreover, we measure the competitor with a *family of loss functions* and compete with the best u measured with the best loss. This adaptivity is achieved through two basic ingredients:

- The Perceptron is independent of scaling of the update by a hypothetical learning rate  $\eta$ , in the sense that the mistakes it does are independent of the scaling. That is, we could update with  $x_{t+1} = x_t + \eta \mathbf{1}[y_t \tilde{y}_t > 0]y_t z_t$  and have the same mistakes and updates because they only depend on the sign of  $\tilde{y}_t$ . Hence, we can think as it is always using the best possible learning rate  $\eta$ .
- The weakened definition of regret allows to consider a family of loss functions, because *the Perceptron is not using any of them in the update*. In this sense, it is worth stressing that the Perceptron algorithm is *not* online subgradient descent on some sequence of loss functions.

Let's now prove the regret guarantee. For the proof, we will need the two following technical lemma.

**Lemma 8.3.** Let 
$$a, c > 0$$
,  $b \ge 0$ , and  $x \ge 0$  such that  $x - a\sqrt{x} \le c$ . Then,  $x \le c + \frac{a^2}{2} + a\sqrt{\frac{a^2}{4} + c}$ .

*Proof.* Let 
$$y=\sqrt{x}$$
, then we have  $y^2-ay-c\leq 0$ . Solving for  $y$  we have  $y\leq \frac{a+\sqrt{a^2+4c}}{2}$ . Hence,  $x=y^2\leq \frac{a^2+2a\sqrt{a^2+4c}+a^2+4c}{4}=\frac{a^2}{2}+\frac{a}{2}\sqrt{a^2+4c}+c$ .

Proof of Theorem 8.2. Denote by the total number of the mistakes of the Perceptron algorithm by  $M = \sum_{t=1}^{T} \mathbf{1}[y_t \tilde{y}_t > 0]$ .

First, note that the Perceptron algorithm can be thought as running Online Subgradient Descent (OSD) with a fixed stepsize  $\eta$  over the losses  $\tilde{\ell}_t(\boldsymbol{x}) = -\langle \mathbf{1}[y_t \tilde{y}_t > 0] y_t \boldsymbol{z}_t, \boldsymbol{x} \rangle$  over  $\mathcal{V} = \mathbb{R}^d$ . Indeed, OSD over such losses would update

$$\boldsymbol{x}_{t+1} = \boldsymbol{x}_t + \eta \mathbf{1}[y_t \tilde{y}_t > 0] y_t \boldsymbol{z}_t. \tag{8.2}$$

Now, as said above,  $\eta$  does not affect in any way the sign of the predictions, hence the Perceptron algorithm could be run with (8.2) and its predictions would be exactly the same. Hence, we have

$$\sum_{t=1}^{T} - \langle \mathbf{1}[y_t \tilde{y}_t > 0] y_t \mathbf{z}_t, \mathbf{x}_t \rangle + \sum_{t=1}^{T} \langle \mathbf{1}[y_t \tilde{y}_t > 0] y_t \mathbf{z}_t, \mathbf{u} \rangle \leq \frac{\|\mathbf{u}\|^2}{2\eta} + \frac{\eta}{2} \sum_{t=1}^{T} \mathbf{1}[y_t \tilde{y}_t > 0] \|\mathbf{z}_t\|_2^2, \ \forall \eta > 0.$$

Given that this inequality holds for any  $\eta$ , we can choose the ones that minimizes the r.h.s., to have

$$\sum_{t=1}^{T} -\langle \mathbf{1}[y_t \tilde{y}_t > 0] y_t \boldsymbol{z}_t, \boldsymbol{x}_t \rangle + \sum_{t=1}^{T} \langle \mathbf{1}[y_t \tilde{y}_t > 0] y_t \boldsymbol{z}_t, \boldsymbol{u} \rangle \leq \|\boldsymbol{u}\| \sqrt{\sum_{t=1}^{T} \mathbf{1}[y_t \tilde{y}_t > 0] \|\boldsymbol{z}_t\|_2^2} \leq \|\boldsymbol{u}\| R \sqrt{\sum_{t=1}^{T} \mathbf{1}[y_t \tilde{y}_t > 0]}.$$
(8.3)

Note that  $-\mathbf{1}[y_t\tilde{y}_t>0]y_t\langle \boldsymbol{z}_t,\boldsymbol{x}_t\rangle\geq 0$ . Also, we have

$$\langle y_t z_t, \boldsymbol{u} \rangle = 1 - (1 - \langle y_t z_t, \boldsymbol{u} \rangle) > 1 - \max(1 - \langle y_t z_t, \boldsymbol{u} \rangle, 0) = 1 - \ell(\langle z_t, \boldsymbol{u} \rangle, y_t).$$

So, denoting by  $\tau_t = \mathbf{1}[y_t \tilde{y}_t > 0]$ , we can rewrite (8.3) as

$$\begin{split} \sum_{t=1}^{T} \tau_{t} &\leq \|\boldsymbol{u}\| R \sqrt{\sum_{t=1}^{T} \tau_{t}} + \sum_{t=1}^{T} \tau_{t} \ell(\langle \boldsymbol{z}_{t}, \boldsymbol{u} \rangle, y_{t}) \\ &\leq \|\boldsymbol{u}\| R \sqrt{\sum_{t=1}^{T} \tau_{t}} + \left(\sum_{t=1}^{T} \tau_{t}^{p}\right)^{1/p} \left(\sum_{t=1}^{T} \ell(\langle \boldsymbol{z}_{t}, \boldsymbol{u} \rangle, y_{t})^{q}\right)^{1/q} \\ &= \|\boldsymbol{u}\| R \sqrt{\sum_{t=1}^{T} \tau_{t}} + \left(\sum_{t=1}^{T} \tau_{t}\right)^{1/p} \left(\sum_{t=1}^{T} \ell(\langle \boldsymbol{z}_{t}, \boldsymbol{u} \rangle, y_{t})^{q}\right)^{1/q}, \end{split}$$

where we used Holder's inequality and  $\frac{1}{p} + \frac{1}{q} = 1$ .

Given that  $M=\sum_{t=1}^T \tau_t$  and denoting by  $L_q=\sum_{t=1}^T \ell^q(\langle {m z}_t, {m u} \rangle, y_t)$ , we have

$$M \le ||u|| R\sqrt{M} + M^{1/p} L_q^{1/q}$$
.

Let's now consider two cases. For q = 1, we can use Lemma 8.3 and have the stated bound. Instead, for q > 1, using Young's inequality (Example 6.22) we have

$$M \le \|\boldsymbol{u}\|R\sqrt{M} + M^{1/p}L_q^{1/q} \le \|\boldsymbol{u}\|R\sqrt{M} + \frac{1}{p}M + \frac{1}{q}L_q,$$

that implies

$$M\left(1-\frac{1}{p}\right) \le \|\boldsymbol{u}\|R\sqrt{M} + \frac{1}{q}L_q$$
.

Using the fact that  $1 - \frac{1}{p} = \frac{1}{q}$ , we have

$$M \le q \|\boldsymbol{u}\| R \sqrt{M} + L_q .$$

Finally, using Lemma 8.3, we have the stated bound.

**Remark 8.4.** The Perceptron algorithm can also be seen as a way to solve the feasibility problem. In particular, consider the problem

Find 
$$\mathbf{x}$$
  
s.t  $\langle \mathbf{q}_i, \mathbf{x} \rangle > 0, i = 1, ..., N$ 

where  $\mathbf{q}_i \in \mathbb{R}^d$ . Essentially, we have a set  $\mathcal{V}$  defined by the intersection of the open half-planes  $\langle \mathbf{q}_i, \mathbf{x} \rangle > 0$  and we want to find any point in it. This is useful, for example, when we have a constrained convex optimization problem over  $\mathcal{V}$  and we need a way to initialize our optimization algorithm.

To use the Perceptron to solve this problem, in each round t we can find one constraint  $q_i$  that is violated and update

$$\boldsymbol{x}_{t+1} = \boldsymbol{x}_t + \boldsymbol{q}_i .$$

The algorithm will find a point in V after  $R^2 \| \mathbf{u} \|_2^2$  iterations, where  $\| \mathbf{q}_i \|_2 \leq R$  and  $\mathbf{u}$  is given by the following optimization problem

$$egin{aligned} m{u} = & rgmin_{m{x} \in \mathbb{R}^d} & \|m{x}\|_2^2 \ & ext{s.t.} & \langle m{q}_i, m{x} 
angle \geq 1, \ i=1,\dots,N \ . \end{aligned}$$

Given that each iteration has complexity proportional to dN, the total complexity is  $\mathcal{O}(dNR^2\|\mathbf{u}\|^2)$ .

## 8.3 History Bits

The Perceptron was proposed by Rosenblatt [1958]. To be more precise, he introduced a *family* of algorithms characterized by a certain architecture. Also, he considered what we call now supervised and unsupervised training procedures. The particular class of Perceptron we use nowadays and I described were called  $\alpha$ -system [Block, 1962]. I hypothesize that the fact the  $\alpha$ -system survived the test of time is exactly due to the simple convergence proof in Block [1962] and Novikoff [1963]. Both proofs are non-stochastic. For the sake of proper credits assignment, it seems that the convergence proof of the Perceptron was proved by many others before Block and Novikoff [see references in Novikoff, 1963]. However, the proof in Novikoff [1963] seems to be the cleanest one. Aizerman et al. [1964] (essentially) described for the first time the Kernel Perceptron and proved a finite mistake bound for it.

The proof of convergence in the non-separable case for q=1 is by Gentile and Littlestone [1999], Gentile [2003] and for q=2 is from Freund and Schapire [1998, 1999a]. The proof presented here is based on the one in Beygelzimer et al. [2017].

### 8.4 Exercises

**Problem 8.1.** in the Perceptron mistake upper bound we let the competitor have any norm and we measure the loss of the competitor with the hinge loss  $\ell^{hinge}(\hat{y},y) = \max(\gamma - \hat{y}y,0)$ , where  $\hat{y} \in \mathbb{R}$  and  $y \in \{-1,1\}$ . Instead, we can equivalently constrain the competitor to have norm equal to 1 and measure the loss with the **hinge loss at margin gamma**:  $\ell^{hinge}_{\gamma}(\hat{y},y) = \frac{1}{\gamma} \max(\gamma - \hat{y}y,0)$ . Prove that  $\ell^{hinge}_{\gamma}(\hat{y},y)$  is still an upper bound on the zero-one loss over the prediction given by  $\mathrm{sign}(\hat{y})$ .

## **Chapter 9**

# **Black-Box Reductions**

In this chapter, we show how to reduce one online learning problem into another in a black-box way. That is, we will use an online convex optimization algorithm to solve a problem different from what it was meant to solve, without looking at its internal working in any way. The only thing we will change will be the input we pass to the algorithm. Why doing it? Because you might have optimization software that you cannot modify or just because designing and analyzing an online learning algorithm in one case might be easier.

### 9.1 Solving Constrained OCO

We might have an Online Convex Optimization (OCO) algorithm designed for constrained online linear optimization over a feasible set  $W \subseteq \mathbb{R}^d$  and we might wonder how we can use it for online convex optimization on a feasible set  $V \subset W$ . How do we deal with the smaller feasible set?

Let's see a prototypical example of this approach. We have a OCO algorithm that outputs in each round  $z_t \in \mathcal{W} = \mathbb{R}^d_{\geq 0}$  and we want to use it for OCO in  $\mathcal{V} = \Delta^{d-1}$ . So, first of all, we have to transform  $z_t$  into a vector of the probability simplex. One way to do it could be to normalize it by its L1 norm. So, we predict in each round by  $x_t = \frac{z_t}{\|z_t\|_1}$  if  $\|z_t\|_1 \neq 0$  and with any other vector in the simplex if  $\|z_t\|_1 = 0$ . Now, we have to find a way to penalize the algorithm every time its prediction is outside  $\mathcal{V}$ , for example passing to it a surrogate loss. In formulas, we have

$$egin{aligned} \operatorname{Regret}_T(oldsymbol{u}) &= \sum_{t=1}^T (\ell_t(oldsymbol{x}_t) - \ell_t(oldsymbol{u})) \leq \sum_{t=1}^T \langle oldsymbol{g}_t, oldsymbol{x}_t - oldsymbol{u} 
angle \ &= \sum_{t=1}^T (\langle oldsymbol{g}_t, oldsymbol{z}_t - oldsymbol{u} 
angle + \langle oldsymbol{g}_t, oldsymbol{x}_t - oldsymbol{z}_t 
angle ), \end{aligned}$$

where  $g_t \in \partial \ell_t(x_t)$ . Now, we want to find  $\hat{g}_t$  such that

$$\langle \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{z}_t \rangle \leq \langle \hat{\boldsymbol{g}}_t, \boldsymbol{z}_t - \boldsymbol{u} \rangle, \ \forall \boldsymbol{u} \in \mathcal{V}$$
.

If we could do it, we would have

$$\operatorname{Regret}_T(oldsymbol{u}) \leq \sum_{t=1}^T \langle oldsymbol{g}_t + \hat{oldsymbol{g}}_t, oldsymbol{z}_t - oldsymbol{u} 
angle,$$

that is the regret of the OCO algorithm on some surrogate linear losses.

Using our definition of  $x_t$ , we have that if  $||z_t||_1 \neq 0$  then

$$\langle \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{z}_t \rangle = \left\langle \boldsymbol{g}_t, \frac{\boldsymbol{z}_t}{\|\boldsymbol{z}_t\|_1} - \boldsymbol{z}_t \right\rangle = \left\langle \boldsymbol{g}_t, \frac{\boldsymbol{z}_t}{\|\boldsymbol{z}_t\|_1} \right\rangle (1 - \|\boldsymbol{z}_t\|_1) = -\langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle \langle [1, \dots, 1]^\top, \boldsymbol{z}_t - \boldsymbol{u} \rangle .$$

Instead, if  $\|\boldsymbol{z}_t\|_1 = 0$  we have

$$\langle \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{z}_t \rangle = \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle = -\langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle \langle [1, \dots, 1]^\top, \boldsymbol{z}_t - \boldsymbol{u} \rangle$$
.

Hence, we have that  $\hat{g_t} = -\langle g_t, x_t \rangle [1, \dots, 1]^{\top}$  and the surrogate linear losses we will pass to the OCO algorithm are

$$\tilde{\ell}_t(\boldsymbol{x}) = \langle \boldsymbol{g}_t - [1, \dots, 1]^\top \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle, \boldsymbol{x} \rangle. \tag{9.1}$$

In this way, we have

$$\operatorname{Regret}_{T}(\boldsymbol{u}) = \sum_{t=1}^{T} (\ell_{t}(\boldsymbol{x}_{t}) - \ell_{t}(\boldsymbol{u})) \leq \sum_{t=1}^{T} (\tilde{\ell}_{t}(\boldsymbol{z}_{t}) - \tilde{\ell}_{t}(\boldsymbol{u})).$$

It is worth noting that the norm of the gradients of the surrogate losses is controlled:  $\|\boldsymbol{g}_t - [1, \dots, 1]^\top \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle\|_{\infty} \le 2\|\boldsymbol{g}_t\|_{\infty}$ .

We solved our problem, but this approach does not seem to scale to arbitrary complex feasible sets. Hence, we need a more general way to solve it. In the following, we will show two complementary ways to do it.

#### 9.1.1 Dealing with Constrains using (Non-Euclidean) Projections

#### Algorithm 9.1 Constrained OCO through (Non-Euclidean) Projections

**Require:** Non-empty closed convex set  $\mathcal{V} \subset \mathbb{R}^d$ , OCO algorithm  $\mathcal{A}$  with feasible set  $\mathcal{W} \supset \mathcal{V}$ , norm  $\|\cdot\|$ , a way to construct surrogate losses  $\tilde{\ell}_t$ 

- 1: for t = 1 to T do
- 2: Get  $z_t \in \mathcal{W}$  from  $\mathcal{A}$
- 3: Output  $oldsymbol{x}_t \in \Pi_{\mathcal{V},\|\cdot\|}(oldsymbol{z}_t)$
- 4: Pay  $\ell_t(\boldsymbol{x}_t)$  for  $\ell_t: \mathcal{V} \to \mathbb{R}$
- 5: Set  $\boldsymbol{g}_t \in \partial \ell_t(\boldsymbol{x}_t)$
- 6: Send the surrogate loss  $\tilde{\ell}_t: V \to \mathbb{R}$  to  $\mathcal{A}$
- 7: end for

Now, we extend the procedure in the previous section to general convex sets and general norms. First of all, we need some definitions and basic results.

**Definition 9.1** (Distance to a set  $\mathcal{V}$  and generalized projection). Let  $V \subset \mathbb{R}^d$  be a convex and closed set. The distance to a set with respect to the norm  $\|\cdot\|$  is the function  $\operatorname{dist}_{\mathcal{V},\|\cdot\|}:\mathbb{R}^d\to\mathbb{R}_{\geq 0}$  defined as  $\operatorname{dist}_{\mathcal{V},\|\cdot\|}(\boldsymbol{x})=\min_{\boldsymbol{y}\in\mathcal{V}}\|\boldsymbol{x}-\boldsymbol{y}\|$ . We also define the generalized projection function  $\Pi_{\mathcal{V},\|\cdot\|}:\mathbb{R}^d\to\mathbb{R}^d$  defined as  $\Pi_{\mathcal{V},\|\cdot\|}\in \operatorname{argmin}_{\boldsymbol{y}\in\mathcal{V}}\|\boldsymbol{x}-\boldsymbol{y}\|$ .

We have the following properties for the distance to a set function.

**Lemma 9.2.** Let V be convex and closed. Then, we have

- $\operatorname{dist}_{\mathcal{V},\|\cdot\|}$  is convex.
- $\operatorname{dist}_{\mathcal{V},\|\cdot\|}$  is 1-Lipschitz with respect to  $\|\cdot\|_{\star}$ .
- $\bullet \ \partial \operatorname{dist}_{\mathcal{V}, \|\cdot\|}(\boldsymbol{x}) = \begin{cases} \{\boldsymbol{g}\} & \boldsymbol{x} \notin V \\ \{\boldsymbol{0}\}, & \boldsymbol{x} \in \mathcal{V} \end{cases}, \text{ where } \|\boldsymbol{g}\|_{\star} = 1 \text{ and } \|\boldsymbol{x} \Pi_{\mathcal{V}, \|\cdot\|}(\boldsymbol{x})\| = \langle \boldsymbol{g}, \boldsymbol{x} \Pi_{\mathcal{V}, \|\cdot\|}(\boldsymbol{x}) \rangle.$

*Proof.* For the first property, we have

$$\begin{split} \operatorname{dist}_{\mathcal{V}, \|\cdot\|}(\lambda \boldsymbol{x} + (1-\lambda)\boldsymbol{z}) &= \min_{\boldsymbol{y} \in \mathcal{V}} \|\lambda \boldsymbol{x} + (1-\lambda)\boldsymbol{z} - \boldsymbol{y}\| \leq \|\lambda \boldsymbol{x} + (1-\lambda)\boldsymbol{z} - (\lambda \Pi_{\mathcal{V}, \|\cdot\|}(\boldsymbol{x}) + (1-\lambda)\Pi_{\mathcal{V}, \|\cdot\|}(\boldsymbol{z})\| \\ &= \|\lambda(\boldsymbol{x} - \Pi_{\mathcal{V}, \|\cdot\|}(\boldsymbol{x})) + (1-\lambda)(\boldsymbol{z} - \Pi_{\mathcal{V}, \|\cdot\|}(\boldsymbol{z}))\| \leq \lambda \operatorname{dist}_{\mathcal{V}, \|\cdot\|}(\boldsymbol{x}) + (1-\lambda)\operatorname{dist}_{\mathcal{V}, \|\cdot\|}(\boldsymbol{z}), \end{split}$$

where in the first inequality we used the convexity of  $\mathcal{V}$ .

For the second property, we have that

$$\begin{aligned} \operatorname{dist}_{\mathcal{V},\|\cdot\|}(\boldsymbol{x}+\boldsymbol{\delta}) - \operatorname{dist}_{\mathcal{V},\|\cdot\|}(\boldsymbol{x}) &= \min_{\boldsymbol{y} \in \mathcal{V}} \ \|\boldsymbol{x}+\boldsymbol{\delta}-\boldsymbol{y}\| - \|\boldsymbol{x} - \Pi_{\mathcal{V},\|\cdot\|}(\boldsymbol{x})\| \leq \|\boldsymbol{x}+\boldsymbol{\delta} - \Pi_{\mathcal{V},\|\cdot\|}(\boldsymbol{x})\| - \|\boldsymbol{x} - \Pi_{\mathcal{V},\|\cdot\|}(\boldsymbol{x})\| \\ &\leq \|\boldsymbol{\delta}\| \ . \end{aligned}$$

For the third property, by the definition of subgradient,  $g \in \partial \operatorname{dist}_{\mathcal{V},\|\cdot\|}(x)$  iff

$$\operatorname{dist}_{\mathcal{V},\|\cdot\|}(z) \geq \operatorname{dist}_{\mathcal{V},\|\cdot\|}(x) + \langle g, z - x \rangle, \ \forall z \in \mathbb{R}^d.$$

Set  $z = \frac{x + \Pi_{\mathcal{V}, \|\cdot\|}(\boldsymbol{x})}{2}$ , so we have

$$\begin{split} \frac{1}{2}\|\boldsymbol{x} - \Pi_{\mathcal{V},\|\cdot\|}(\boldsymbol{x})\| &= \|\boldsymbol{z} - \boldsymbol{x}\| \geq \min_{\boldsymbol{y} \in \mathcal{V}} \|\boldsymbol{z} - \boldsymbol{y}\| = \operatorname{dist}_{\mathcal{V},\|\cdot\|}(\boldsymbol{z}) \geq \operatorname{dist}_{\mathcal{V},\|\cdot\|}(\boldsymbol{x}) + \langle \boldsymbol{g}, \boldsymbol{z} - \boldsymbol{x} \rangle \\ &= \|\boldsymbol{x} - \Pi_{\mathcal{V},\|\cdot\|}(\boldsymbol{x})\| + \frac{1}{2} \langle \boldsymbol{g}, \Pi_{\mathcal{V},\|\cdot\|}(\boldsymbol{x}) - \boldsymbol{x} \rangle, \end{split}$$

that implies

$$\|\boldsymbol{x} - \Pi_{\mathcal{V},\|\cdot\|}(\boldsymbol{x})\| \leq \langle \boldsymbol{g}, \boldsymbol{x} - \Pi_{\mathcal{V},\|\cdot\|}(\boldsymbol{x}) \rangle$$
.

Using the fact that  $\operatorname{dist}_{\mathcal{V},\|\cdot\|}$  is 1-Lipschitz, we have that g satisfies  $\|g\|_{\star}=1$  and  $\|x-\Pi_{\mathcal{V},\|\cdot\|}(x)\|=\langle g,x-\Pi_{\mathcal{V},\|\cdot\|}(x)\rangle$ .

**Example 9.3.** If we consider the L2 norm, we have

$$\partial \operatorname{dist}_{\mathcal{V},\|\cdot\|_2}(\boldsymbol{x}) = egin{cases} \left\{ rac{\boldsymbol{x} - \Pi_{\mathcal{V}}(\boldsymbol{x})}{\|\boldsymbol{x} - \Pi_{\mathcal{V}}(\boldsymbol{x})\|_2} 
ight\} & \boldsymbol{x} 
otin V \ \{\mathbf{0}\}, & \boldsymbol{x} \in \mathcal{V} \end{cases},$$

where  $\Pi_{\mathcal{V}}$  is the standard Euclidean projection.

**Example 9.4.** Note that the projection with respect to a norm different than L2 does not have to be unique. For example, we consider the L1 norm and  $V = \Delta^{d-1}$  and we have that

$$\Pi_{\mathcal{V},\|\cdot\|_1}(\boldsymbol{x}) = \underset{\boldsymbol{y} \in \Delta^{d-1}}{\operatorname{argmin}} \|\boldsymbol{x} - \boldsymbol{y}\|_1.$$

From this, we can see that the generalized projection is not unique. In fact, if  $x_i > 1$  for i = 1, ..., d, then  $\underset{\boldsymbol{y} \in \Delta^{d-1}}{\operatorname{argmin}} \|\boldsymbol{x} - \boldsymbol{y}\|_1 = \Delta^{d-1}$ . Indeed, we have

$$\underset{\boldsymbol{y} \in \Delta^{d-1}}{\operatorname{argmin}} \|\boldsymbol{x} - \boldsymbol{y}\|_{1} = \underset{\boldsymbol{y} \in \Delta^{d-1}}{\operatorname{argmin}} \sum_{i=1}^{d} |x_{i} - y_{i}| = \underset{\boldsymbol{y} \in \Delta^{d-1}}{\operatorname{argmin}} \sum_{i=1}^{d} (x_{i} - y_{i}) = \underset{\boldsymbol{y} \in \Delta^{d-1}}{\operatorname{argmin}} \sum_{i=1}^{d} x_{i} - 1,$$

that is constant with respect to y. Similarly, if  $x_i \leq 0$ , then  $\operatorname{argmin}_{y \in \Delta^{d-1}} \|x - y\|_1 = \Delta^{d-1}$  because

$$\underset{\boldsymbol{y} \in \Delta^{d-1}}{\operatorname{argmin}} \|\boldsymbol{x} - \boldsymbol{y}\|_{1} = \underset{\boldsymbol{y} \in \Delta^{d-1}}{\operatorname{argmin}} \sum_{i=1}^{d} |x_{i} - y_{i}| = \underset{\boldsymbol{y} \in \Delta^{d-1}}{\operatorname{argmin}} \sum_{i=1}^{d} (y_{i} - x_{i}) = \underset{\boldsymbol{y} \in \Delta^{d-1}}{\operatorname{argmin}} 1 - \sum_{i=1}^{d} x_{i}.$$

From the optimality condition, we have that  $z = \prod_{\mathcal{V}, \|\cdot\|_1}(x)$  iff

$$\mathbf{0} \in N_{\mathcal{V}}(\boldsymbol{z}) + \partial \|\boldsymbol{x} - \boldsymbol{z}\|_{1},$$

where  $N_{\mathcal{V}}(z)$  is the normal cone to  $\mathcal{V}$  in z, that is

$$N_{\mathcal{V}}(\boldsymbol{z}) = \{ \alpha \mathbf{1} + \sum_{i: z_i = 0} \beta_i \boldsymbol{e}_i : \alpha \in \mathbb{R}, \beta_i \leq 0 \}.$$

This implies that if  $S_1 = \{ \boldsymbol{x} : x_i \geq z_i, \boldsymbol{x} \in \Delta^{d-1} \}$  and  $S_2 = \{ \boldsymbol{x} : x_i \leq z_i, \boldsymbol{x} \in \Delta^{d-1} \}$  are non-empty then they contain solutions of the generalized projection. In particular, if  $\|\boldsymbol{z}\|_1 < 1$  then  $S_1 \neq \{\}$  and if  $\|\boldsymbol{z}\|_1 > 1$  and  $z_i \geq 0$  then  $S_2 \neq \{\}$ . This implies that if  $\boldsymbol{x} \in \mathbb{R}^d_{\geq 0}$  then, for example,  $\frac{\boldsymbol{x}}{\|\boldsymbol{x}\|_1} \in \Pi_{\Delta^{d-1},\|\cdot\|_1}(\boldsymbol{x})$  when  $\|\boldsymbol{x}\|_1 > 0$  and  $\Pi_{\Delta^{d-1},\|\cdot\|_1}(\boldsymbol{x}) = \Delta^{d-1}$  if  $\|\boldsymbol{x}\|_1 = 0$ . Moreover, we can also calculate a subgradient  $\boldsymbol{q}$  of  $\operatorname{dist}_{\Delta^{d-1},\|\cdot\|_1}(\boldsymbol{x})$  as  $[-1,\ldots,-1]$  if  $\boldsymbol{x} \in S_1$  and  $[1,\ldots,1]$  if  $\boldsymbol{x} \in S_2$ .

We can now state the main theorem.

**Theorem 9.5.** Denote by Regret $_T^{\mathcal{A}}(u)$  the regret of an OCO algorithm  $\mathcal{A}$  with feasible set  $\mathcal{W} \subseteq \mathbb{R}^d$ . Let  $\mathcal{V} \subset \mathcal{W}$  be convex and closed and  $q_t \in \partial \operatorname{dist}_{\mathcal{V},\|\cdot\|}(x_t)$ , and the following choices of surrogate losses  $\tilde{\ell}_t : V \to \mathbb{R}$ :

- $\tilde{\ell}_t(x) = \langle g_t, x \rangle + \|g_t\|_{\star} \operatorname{dist}_{\mathcal{V}, \|\cdot\|}(x)$
- $\tilde{\ell}_t(x) = \langle g_t + ||g_t||_{\star} q_t, x \rangle$
- $\tilde{\ell}_t(\boldsymbol{x}) = \langle \boldsymbol{g}_t, \boldsymbol{x} \rangle + \max(\langle \boldsymbol{g}_t, \frac{\boldsymbol{x}_t \boldsymbol{z}_t}{\|\boldsymbol{x}_t \boldsymbol{z}_t\|} \rangle, 0) \operatorname{dist}_{\mathcal{V}, \|\cdot\|}(\boldsymbol{x})$
- $\tilde{\ell}_t(\boldsymbol{x}) = \langle \boldsymbol{g}_t + \max(\langle \boldsymbol{g}_t, \frac{\boldsymbol{x}_t \boldsymbol{z}_t}{\|\boldsymbol{x}_t \boldsymbol{z}_t\|} \rangle, 0) \boldsymbol{q}_t, \boldsymbol{x} \rangle$ .

Then, for any of the surrogate losses Algorithm 9.1 guarantees

$$\operatorname{Regret}_T(\boldsymbol{u}) = \sum_{t=1}^T (\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) \leq \operatorname{Regret}_T^{\mathcal{A}}(\boldsymbol{u}), \ \forall \boldsymbol{u} \in \mathcal{V}.$$

Moreover, for any  $\tilde{\boldsymbol{g}}_t \in \partial \tilde{\ell}_t(\boldsymbol{x}_t)$  we have  $\|\tilde{\boldsymbol{g}}_t\|_{\star} \leq 2\|\boldsymbol{g}_t\|_{\star}$ .

*Proof.* Note that the second and fourth surrogates are just linearization of the first and third surrogate losses, respectively. Hence, it is enough to prove the regret guarantee for the first and third surrogate loss.

For all of them, we start by observing that

$$\operatorname{Regret}_{T}(\boldsymbol{u}) = \sum_{t=1}^{T} (\ell_{t}(\boldsymbol{x}_{t}) - \ell_{t}(\boldsymbol{u})) \leq \sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{u} \rangle$$
$$= \sum_{t=1}^{T} (\langle \boldsymbol{g}_{t}, \boldsymbol{z}_{t} - \boldsymbol{u} \rangle + \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{z}_{t} \rangle). \tag{9.2}$$

For the first surrogate loss, we have

$$\begin{split} \sum_{t=1}^{T} (\langle \boldsymbol{g}_t, \boldsymbol{z}_t - \boldsymbol{u} \rangle + \langle \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{z}_t \rangle) &\leq \sum_{t=1}^{T} (\langle \boldsymbol{g}_t, \boldsymbol{z}_t - \boldsymbol{u} \rangle + \|\boldsymbol{g}_t\|_{\star} \|\boldsymbol{z}_t - \boldsymbol{x}_t\|) \\ &= \sum_{t=1}^{T} (\langle \boldsymbol{g}_t, \boldsymbol{z}_t - \boldsymbol{u} \rangle + \|\boldsymbol{g}_t\|_{\star} \min_{\boldsymbol{y} \in \mathcal{V}} \|\boldsymbol{z}_t - \boldsymbol{y}\|) \\ &= \sum_{t=1}^{T} (\tilde{\ell}_t(\boldsymbol{z}_t) - \tilde{\ell}_t(\boldsymbol{u})) \,. \end{split}$$

For the third surrogate loss, first of all observe that this loss is convex because  $\operatorname{dist}_{\mathcal{V},\|\cdot\|}$  is multiplied by a non-negative number. In the case that  $\langle \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{z}_t \rangle \leq 0$ , the second term in (9.2) is negative, so we can drop it. For the case that  $\langle \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{z}_t \rangle > 0$ , we have

$$egin{aligned} \left\langle oldsymbol{g}_t, oldsymbol{z}_t - oldsymbol{u} 
ight
angle + \left\langle oldsymbol{g}_t, oldsymbol{z}_t - oldsymbol{z}_t 
ight) + \left\langle oldsymbol{g}_t, oldsymbol{z}_t - oldsymbol{z}_t 
ight) + \left\langle oldsymbol{g}_t, oldsymbol{x}_t - oldsymbol{z}_t 
ight| \\ &= \left\langle oldsymbol{g}_t, oldsymbol{z}_t - oldsymbol{u} 
ight
angle + \left\langle oldsymbol{g}_t, oldsymbol{x}_t - oldsymbol{z}_t 
ight| \\ &= \left\langle oldsymbol{g}_t, oldsymbol{z}_t - oldsymbol{u} 
ight
angle + \left\langle oldsymbol{g}_t, oldsymbol{x}_t - oldsymbol{z}_t 
ight| \\ &= \left\langle oldsymbol{g}_t, oldsymbol{z}_t - oldsymbol{u} 
ight
angle + \left\langle oldsymbol{g}_t, oldsymbol{x}_t - oldsymbol{z}_t 
ight
angle \\ &= \left\langle oldsymbol{g}_t, oldsymbol{z}_t - oldsymbol{u} 
ight
angle + \left\langle oldsymbol{g}_t, oldsymbol{z}_t - oldsymbol{z}_t 
ight
angle \\ &= \left\langle oldsymbol{g}_t, oldsymbol{z}_t - oldsymbol{u} 
ight
angle + \left\langle oldsymbol{g}_t, oldsymbol{z}_t - oldsymbol{z}_t 
ight
angle \\ &= \left\langle oldsymbol{g}_t, oldsymbol{z}_t - oldsymbol{z}_t 
ight
angle + \left\langle oldsymbol{g}_t, oldsymbol{z}_t - oldsymbol{z}_t 
ight
angle \\ &= \left\langle oldsymbol{g}_t, oldsymbol{z}_t - oldsymbol{z}_t 
ight
angle + \left\langle oldsymbol{g}_t, oldsymbol{z}_t - oldsymbol{z}_t 
ight
angle + \left\langle oldsymbol{g}_t, oldsymbol{z}_t - oldsymbol{z}_t 
ight
angle \\ &= \left\langle oldsymbol{g}_t, oldsymbol{z}_t - oldsymbol{z}_t 
ight
angle + \left\langle oldsymbol{g}_t, oldsymbol{z}_t - oldsymbol{z}_t 
ight
angle \\ &= \left\langle oldsymbol{g}_t, oldsymbol{z}_t, oldsymbol{z}_t - oldsymbol{z}_t 
ight
angle + \left\langle oldsymbol{g}_t, oldsymbol{g}_t, oldsymbol{z}_t 
ight
angle \\ &= \left\langle oldsymbol{g}_t, oldsymbol{g}_t, oldsymbol{z}_t 
ight
angle + \left\langle oldsymbol{g}_t, oldsymbol{g$$

Remembering that  $\|\boldsymbol{q}_t\|_{\star}=1$  we also have in all cases that  $\|\tilde{\boldsymbol{g}}_t\|_{\star}\leq 2\|\boldsymbol{g}_t\|_{\star}$ .

**Remark 9.6.** In the case that  $\|\cdot\| = \|\cdot\|_2$ , we can sharpen the bound on the norm of  $\tilde{\boldsymbol{g}}_t$  for the third and fourth loss. In fact, we have  $\boldsymbol{q}_t = \frac{\boldsymbol{z}_t - \boldsymbol{x}_t}{\|\boldsymbol{z}_t - \boldsymbol{x}_t\|_2}$  and

$$\| ilde{oldsymbol{g}}_t\|^2 = \|oldsymbol{g}_t\|_2^2 - \left(\left\langle oldsymbol{g}_t, rac{oldsymbol{x}_t - oldsymbol{z}_t}{\|oldsymbol{x}_t - oldsymbol{z}_t\|_2}
ight)^2 \leq \|oldsymbol{g}_t\|_2^2 \ .$$

**Remark 9.7.** The first surrogate loss has a very natural interpretation: it is a Lipschitz penalty function that we add to the (linearized) original losses, where the Lipschitz constant is the same of the original function. Hence, we essentially penalize the algorithm for predicting a point outside of the feasible set.

**Remark 9.8.** In the case that the loss functions  $\ell_t$  satisfies a weaker form of strong convexity, we can show that the black-box reduction will preserve it. In particular, consider the case that we use an online learning algorithm with feasible set W with bounded diameter D with respect to the L2 norm, the losses  $\ell_t$  are L-Lipschitz on V with respect to the L2 norm and they also satisfies

$$\ell_t(m{x}) - \ell_t(m{u}) \leq \langle m{g}, m{x} - m{u} 
angle - rac{eta}{2} \langle m{g}, m{x} - m{u} 
angle^2, \ orall m{u}, m{x} \in \mathcal{V}, m{g} \in \partial \ell(m{x}),$$

where  $\beta \leq \frac{1}{DL}$ . For example, we saw that if the functions  $\ell_t$  are exp-concave, that the above is true. Now, use projections with respect to the L2 norm onto V, and the fourth surrogate loss in Theorem 9.5, so we have

$$\langle \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{u} \rangle \leq \langle \tilde{\boldsymbol{g}}_t, \boldsymbol{z}_t - \boldsymbol{u} \rangle, \ \forall \boldsymbol{u} \in \mathcal{V},$$

and  $\|\tilde{\boldsymbol{g}}_t\|_2 \leq \|\boldsymbol{g}_t\|_2 \leq L$ . Hence, we have  $\langle \tilde{\boldsymbol{g}}_t, \boldsymbol{z}_t - \boldsymbol{u} \rangle \leq \|\tilde{\boldsymbol{g}}_t\|_2 \|\boldsymbol{z}_t - \boldsymbol{u}\|_2 \leq LD \leq \frac{1}{\beta}$  for all  $\boldsymbol{u} \in \mathcal{V}$ , that implies

$$\ell_t(oldsymbol{x}_t) - \ell_t(oldsymbol{u}) \leq \langle oldsymbol{g}_t, oldsymbol{x}_t - oldsymbol{u} 
angle - rac{eta}{2} \langle oldsymbol{g}_t, oldsymbol{x}_t - oldsymbol{u} 
angle^2 \leq \langle oldsymbol{ ilde{g}}_t, oldsymbol{z}_t - oldsymbol{u} 
angle - rac{eta}{2} \langle oldsymbol{ ilde{g}}_t, oldsymbol{z}_t - oldsymbol{u} 
angle^2, \ orall oldsymbol{u} \in \mathcal{V},$$

where the second inequality is due to the fact that  $x \to x - \frac{\beta}{2} x^2$  is increasing for  $x \in [0, \frac{1}{\beta}]$ .

**Example 9.9.** Let's start with a simple example: We have an online algorithm that works in  $\mathbb{R}$  and we want to constrain it to  $\mathbb{R}_{\geq 0}$ . In this case, the choice of the norms does not really matter, we can choose L2. The projection is simply  $x_t = \max(z_t, 0)$ . The subgradient  $q_t$  of the distance function can be chosen as

$$q_t = \begin{cases} -1, & z_t < 0\\ 0, & z_t \ge 0 \end{cases}$$

So, using the fourth surrogate loss function in Theorem 9.5, the surrogate linear losses are  $\tilde{\ell}_t(x) = \tilde{g}_t x$  where

$$\tilde{g}_t = \begin{cases} \min(g_t, 0), & z_t < 0 \\ g_t, & z_t \ge 0 \end{cases}$$

**Example 9.10** (Regret Matching+). Consider a OGD with learning rate  $\eta = \frac{\alpha}{\sqrt{T}}$ , over the feasible set  $\mathcal{V} = \mathbb{R}^d_{\geq 0}$  and with initial prediction  $\mathbf{x}_1 = \mathbf{0}$ . Its regret upper bound is

$$\sum_{t=1}^{T} \langle \boldsymbol{g}_t, \boldsymbol{z}_t - \boldsymbol{u} \rangle \leq \frac{1}{2} \left( \frac{\|\boldsymbol{u}\|_2^2}{\alpha} + \alpha \max_t \|\boldsymbol{g}_t\|_2^2 \right) \sqrt{T}, \ \forall \boldsymbol{u} \in \mathcal{V} \ .$$

Now, using the observations in Example 9.4, we can project onto  $\Delta^{d-1}$  with respect to the  $L_1$  norm, using

$$oldsymbol{x}_t = egin{cases} rac{oldsymbol{z}_t}{\|oldsymbol{z}_t\|_1}, & oldsymbol{z}_t 
eq oldsymbol{0} \ [1/d, \dots, 1/d]^ op, & oldsymbol{z}_t = oldsymbol{0} \end{cases}.$$

Then, using any of the above surrogate losses in Algorithm 9.1, we have

$$\sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{u} \rangle \leq \frac{1}{2} \left( \frac{\|\boldsymbol{u}\|_{2}^{2}}{\alpha} + \alpha \max_{t} \|\tilde{\boldsymbol{g}}_{t}\|_{2}^{2} \right) \sqrt{T}, \ \forall \boldsymbol{u} \in \Delta^{d-1},$$

and  $\|\tilde{\boldsymbol{g}}_t\|_2 \leq \sqrt{d} \|\tilde{\boldsymbol{g}}_t\|_{\infty} \leq 2\sqrt{d} \|\boldsymbol{g}_t\|_{\infty}$ . Choosing  $\alpha$  proportional to  $\sqrt{d}$  gives an upper bound proportional to  $\sqrt{dT}$ , that is the expected one when using an algorithm with a Euclidean geometry.

However, we can do even better! Choose the specific surrogate losses in (9.1) with the projection  $\frac{z_t}{\|z_t\|_1}$ , then it should be easy to realize that  $x_t$  is independent of  $\eta > 0$  (left as an exercise for the reader). This means that we can set  $\eta = 1$  but the regret guarantee of the resulting algorithm will be the one corresponding to the best  $\eta > 0$  in hindsight:

$$\sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{u} \rangle \leq \min_{\eta > 0} \frac{\|\boldsymbol{u}\|_{2}^{2}}{2\eta} + \frac{\eta}{2} \sum_{t=1}^{T} \|\boldsymbol{g}_{t} - \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} \rangle\|_{2}^{2}$$

$$\leq \|\boldsymbol{u}\|_{2} \sqrt{\sum_{t=1}^{T} \|\boldsymbol{g}_{t} - \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} \rangle\|_{2}^{2}}$$

$$\leq 2\sqrt{dT \max_{t} \|\boldsymbol{g}_{t}\|_{\infty}}, \ \forall \boldsymbol{u} \in \Delta^{d-1}.$$

The resulting algorithm is known as Regret Matching+ and, despite the suboptimal dependency on d, this is one of the best performing algorithm in practice for the setting of learning with expert advice. If instead of projected OGD we use FTRL with a fixed squared L2 regularizer and feasible set  $\mathcal{V} = \mathbb{R}^d_{\geq 0}$ , we obtain the original Regret Matching algorithm, see Exercise 9.2.

#### 9.1.2 Dealing with Constrains using Bregman Projections

Now, we show an alternative approach based on Bregman projections. First, we define the concept of Bregman projection.

**Definition 9.11** (Bregman Projection). Let  $\psi: \mathcal{X} \times \operatorname{int} \mathcal{X} \to \mathbb{R}_{\geq 0}$  be strictly convex with respect to  $\|\cdot\|$  and differentiable with in the interior of  $\mathcal{X}$ . Assume  $\mathcal{V} \subset \mathcal{X}$  to be convex and closed. Then, we define the Bregman projection as

$$\Pi_{\mathcal{V},B_{\psi}}(\boldsymbol{x}) = \underset{\boldsymbol{y} \in \mathcal{V}}{\operatorname{argmin}} \ B_{\psi}(\boldsymbol{y};\boldsymbol{x}) .$$

With this new concept of projection, we can state the following theorem.

**Theorem 9.12.** Let  $\psi : \mathcal{X} \times \operatorname{int} \mathcal{X} \to \mathbb{R}_{\geq 0}$  be  $\mu$ -strongly convex with respect to  $\|\cdot\|$  and  $\beta$ -smooth with respect to  $\|\cdot\|_*$ . Assume  $\mathcal{V} \subset \mathcal{X}$  to be convex and closed. Consider Algorithm 9.1, where we use the Bregman projection and the surrogate losses

$$ilde{\ell}_t(oldsymbol{x}) = \left\langle oldsymbol{g}_t + \max\left(0, rac{\langle oldsymbol{g}_t, oldsymbol{x}_t - oldsymbol{z}_t 
angle}{\mu \|oldsymbol{x}_t - oldsymbol{z}_t\|^2} 
ight) (
abla \psi(oldsymbol{z}_t) - 
abla \psi(oldsymbol{x}_t), oldsymbol{x} 
ight
angle \ .$$

Then, we have

$$\operatorname{Regret}_T(\boldsymbol{u}) = \sum_{t=1}^T (\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) \leq \operatorname{Regret}_T^{\mathcal{A}}(\boldsymbol{u}), \ \forall \boldsymbol{u} \in \mathcal{V}.$$

Moreover, we have  $\|\tilde{\boldsymbol{g}}_t\|_\star \leq \left(1 + \frac{\beta}{\mu}\right) \|\boldsymbol{g}_t\|_\star$  for any  $\tilde{\boldsymbol{g}}_t \in \tilde{\ell}_t(\boldsymbol{x})$ .

Proof. Once again, we have

$$egin{aligned} \operatorname{Regret}_T(oldsymbol{u}) &= \sum_{t=1}^T (\ell_t(oldsymbol{x}_t) - \ell_t(oldsymbol{u})) \leq \sum_{t=1}^T \langle oldsymbol{g}_t, oldsymbol{x}_t - oldsymbol{u} 
angle \ &= \sum_{t=1}^T (\langle oldsymbol{g}_t, oldsymbol{z}_t - oldsymbol{u} 
angle + \langle oldsymbol{g}_t, oldsymbol{x}_t - oldsymbol{z}_t 
angle ) \ . \end{aligned}$$

Moreover, we have

$$egin{aligned} \langle oldsymbol{g}_t, oldsymbol{x}_t - oldsymbol{z}_t 
angle & \leq \max\left(0, rac{\langle oldsymbol{g}_t, oldsymbol{x}_t - oldsymbol{z}_t 
angle}{\mu \|oldsymbol{x}_t - oldsymbol{z}_t \|^2} 
ight) \mu \|oldsymbol{x}_t - oldsymbol{z}_t \|^2 \ & \leq \max\left(0, rac{\langle oldsymbol{g}_t, oldsymbol{x}_t - oldsymbol{z}_t 
angle}{\mu \|oldsymbol{x}_t - oldsymbol{z}_t \angle} 
ight) \langle \nabla \psi(oldsymbol{z}_t) - \nabla \psi(oldsymbol{x}_t), oldsymbol{z}_t - oldsymbol{x}_t 
angle, \end{aligned}$$

where in the second inequality we used the strong convexity of  $\psi$ . Hence, we have

$$\begin{split} \langle \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{u} \rangle &\leq \langle \boldsymbol{g}_t, \boldsymbol{z}_t - \boldsymbol{u} \rangle + \max \left( 0, \frac{\langle \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{z}_t \rangle}{\mu \|\boldsymbol{x}_t - \boldsymbol{z}_t\|^2} \right) \langle \nabla \psi(\boldsymbol{z}_t) - \nabla \psi(\boldsymbol{x}_t), \boldsymbol{z}_t - \boldsymbol{x}_t \rangle \\ &\leq \left\langle \boldsymbol{g}_t + \max \left( 0, \frac{\langle \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{z}_t \rangle}{\mu \|\boldsymbol{x}_t - \boldsymbol{z}_t\|^2} \right) (\nabla \psi(\boldsymbol{z}_t) - \nabla \psi(\boldsymbol{x}_t)), \boldsymbol{z}_t - \boldsymbol{u} \right\rangle, \end{split}$$

where in the second inequality we used the first-order optimality condition

$$\langle \nabla \psi(\boldsymbol{z}_t) - \nabla \psi(\boldsymbol{x}_t), \boldsymbol{u} - \boldsymbol{x}_t \rangle \leq 0, \ \forall \boldsymbol{u} \in \mathcal{V}.$$

For the bound on  $\|\tilde{g}_t\|_{\star}$  observe that

$$\begin{split} \|\tilde{\boldsymbol{g}}_t\|_{\star} &= \left\| \boldsymbol{g}_t + \max\left(0, \frac{\langle \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{z}_t \rangle}{\mu \|\boldsymbol{x}_t - \boldsymbol{z}_t\|^2}\right) (\nabla \psi(\boldsymbol{z}_t) - \nabla \psi(\boldsymbol{x}_t)) \right\|_{\star} \\ &\leq \|\boldsymbol{g}_t\|_{\star} + \max\left(0, \frac{\langle \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{z}_t \rangle}{\mu \|\boldsymbol{x}_t - \boldsymbol{z}_t\|^2}\right) \|\nabla \psi(\boldsymbol{z}_t) - \nabla(\boldsymbol{x}_t)\|_{\star} \\ &\leq \|\boldsymbol{g}_t\|_{\star} + \max\left(0, \frac{\langle \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{z}_t \rangle}{\mu \|\boldsymbol{x}_t - \boldsymbol{z}_t\|^2}\right) \beta \|\boldsymbol{z}_t - \boldsymbol{x}_t\| \\ &\leq \left(1 + \frac{\beta}{\mu}\right) \|\boldsymbol{g}_t\|_{\star}. \end{split}$$

**Example 9.13.** Let's calculate  $\Pi_{\Delta^{d-1},B_{\psi}}(x)$  where  $x \in \mathbb{R}^d_{>0}$ ,  $\psi(x) = \sum_{i=1}^d x_i \ln x_i$ , and we define  $0 \ln 0 = 0$ . Hence, we have to solve the following optimization problem

$$\underset{\mathbf{y} \in \Delta^{d-1}}{\operatorname{argmin}} \sum_{i=1}^{d} y_i \ln \frac{y_i}{x_i} .$$

We can rewrite it as an unconstrained optimization reformulating the problem over d-1 variables, as

$$\underset{\boldsymbol{y} \in \mathbb{R}_{\geq 0}^{d-1}}{\operatorname{argmin}} \ \sum_{i=1}^{d-1} y_i \ln \frac{x_i}{y_i} + \left(1 - \sum_{i=1}^{d-1} y_i\right) \ln \frac{1 - \sum_{i=1}^{d-1} y_i}{x_d} \ .$$

Note that the constraint on  $y_1, \ldots, y_{d-1}$  and  $1 - \sum_{i=1}^{d-1} y_i$  to be non-negative is enforced by the domain of the logarithm. This is now an unconstrained convex optimization problem, so we can solve it equating the gradient of the objective function to zero. Hence, we have

$$\ln \frac{y_i}{x_i} + 1 - \ln \frac{1 - \sum_{j=1}^{d-1} y_j}{x_d} - 1 = 0, \ i = 1, \dots, d - 1,$$

that gives

$$y_i = x_i \frac{1 - \sum_{j=1}^{d-1} y_j}{x_d}, \ i = 1, \dots, d-1.$$
 (9.3)

Summing over  $i=1,\ldots,d-1$ , we have  $\sum_{i=1}^{d-1}y_i=\frac{1-\sum_{i=1}^{d-1}y_i}{x_d}\sum_{i=1}^{d-1}x_i$ . Solving it, we have  $\frac{1-\sum_{i=1}^{d-1}y_i}{x_d}=\frac{1}{\sum_{i=1}^{d}x_i}$  and using it in (9.3) gives  $y_i=\frac{x_i}{\sum_{j=1}^{d}x_j}$ , for  $i=1,\ldots,d$ .

#### 9.2 **Sleeping Experts**

Consider now the setting of learning with expert where only a subset of the experts is active in each round. In particular we have that  $a_{t,i} = 1$  if expert i is active at time t, and  $a_{t,i} = 0$  if the expert is inactive, that is, sleeping. This setting is useful in the case that some experts might become unavailable in some rounds, but also to model the case that the set of experts is growing over time.

The online algorithm receives at the beginning of each round the information about which experts will be active and it can pick only one of the active experts. So, we constraint the learning with expert algorithm to produce a probability distribution only over the active experts. So, we will use a different notion of regret, in particular our regret with respect to any expert i is defined as

$$\operatorname{Regret}_T^{\operatorname{sleeping}}(\boldsymbol{e}_i) := \sum_{t=1}^T a_{t,i} (\langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle - g_{t,i}).$$

In words, we measure the regret against expert i only on rounds where the expert was active. This notion can be easily generalized to an arbitrary convex combination u of experts as

$$\operatorname{Regret}_{T}^{\operatorname{sleeping}}(\boldsymbol{u}) := \sum_{t=1}^{T} \sum_{i=1}^{d} u_{i} a_{t,i} (\langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} \rangle - g_{t,i}), \ \forall \boldsymbol{u} \in \Delta^{d-1} \ .$$

In the case that all the experts are active on all rounds, this notion recovers the usual one. However, in the general case this is a different notion than the one we used in OLO.

For the reduction, we need a way to transform a vector  $z_t \in \mathbb{R}^d_{\geq 0}$  into a vector in the simplex defined by the active experts, and we also need appropriate surrogate losses. The reduction will be similar to the one we used last time. For the first part, we construct a probability distribution as

$$x_{t,i} = \frac{a_{t,i}z_{t,i}}{\sum_{i=1}^{d} a_{t,j}z_{t,j}}, \ \forall i = 1, \dots, d.$$

For the second part, from the original linear losses  $\ell_t(x) = \langle g_t, x \rangle$  we construct the modified losses  $\ell_t(x) = \langle \tilde{g}_t, x \rangle$ , where  $\tilde{g}_{t,i} = a_{t,i}(g_{t,i} - \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle)$ . The overall algorithm is in Algorithm 9.2.

#### Algorithm 9.2 Sleeping Experts Reductions

**Require:** Online linear optimization algorithm  $\mathcal{A}$  with feasible set  $\mathcal{V} = \mathbb{R}^d_{\geq 0}$ 

- 1: for t = 1 to T do
- 2:
- Get  $z_t \in \mathbb{R}^d_{\geq 0}$  from  $\mathcal{A}$ Receive the state of the experts  $a_{t,i} \in \{0,1\}, i=1,\ldots,d$ Output  $x_{t,i} = \frac{a_{t,i}z_{t,i}}{\sum_{j=1}^d a_{t,j}z_{t,j}}, \ i=1,\ldots,d$ 3:
- Pay  $\ell_t(\boldsymbol{x}_t) = \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle$
- Send the surrogate loss  $\tilde{\ell}_t(\mathbf{x}) = \langle \tilde{\mathbf{g}}_t, \mathbf{x} \rangle$  to  $\mathcal{A}$ , where  $\tilde{g}_{t,i} = a_{t,i}(g_{t,i} \langle \mathbf{g}_t, \mathbf{x}_t \rangle), i = 1, \dots, d$
- 7: end for

With the above definitions, we have

$$\langle \tilde{\boldsymbol{g}}_t, \boldsymbol{z}_t \rangle = \sum_{i=1}^d a_{t,i} (g_{t,i} - \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle) z_{t,i} = \left( \sum_{j=1}^d a_{t,j} z_{t,j} \right) \sum_{i=1}^d x_{t,i} (g_{t,i} - \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle) = 0 .$$

In turn, this implies that

$$a_{t,i}(\langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle - g_{t,i}) = \langle \tilde{\boldsymbol{g}}_t, \boldsymbol{z}_t \rangle + a_{t,i}(\langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle - g_{t,i}) = \langle \tilde{\boldsymbol{g}}_t, \boldsymbol{z}_t \rangle - \tilde{g}_{t,i}, \ i = 1, \dots, d.$$

In words, we can construct surrogate losses to transform the sleeping expert problem in an OLO problem over  $\mathbb{R}^d_{>0}$ , obtaining that

$$\operatorname{Regret}_{T}^{\operatorname{sleeping}}(\boldsymbol{u}) = \sum_{t=1}^{T} \sum_{i=1}^{d} u_{i} a_{t,i} (\langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} \rangle - g_{t,i}) = \sum_{t=1}^{T} \langle \tilde{\boldsymbol{g}}_{t}, \boldsymbol{z}_{t} - \boldsymbol{u} \rangle, \forall \boldsymbol{u} \in \Delta^{d-1}.$$

The norm of the surrogate losses is controlled because  $\|\tilde{g}_t\|_{\infty} \leq 2\|g_t\|_{\infty}$ .

Remark 9.14. Clearly, if we have an algorithm for learning with experts, we can use it in the reduction because  $\Delta^{d-1} \subset \mathbb{R}^d_{>0}$ .

**Remark 9.15.** The above definitions and reduction generalize to the setting that  $a_{t,i} \in [0,1]$ , denoting the confidence that the expert has in their prediction, where 0 means that the expert has no confidence and it abstains from producing a prediction.

#### 9.3 Reduction to Magnitude and Direction

Here, we will see how to extend a 1-dimensional algorithm for unconstrained OCO to a OCO in any number of dimensions and using any (reasonable) norm.

This reduction requires an unconstrained OCO algorithm for the 1-dimensional case and an algorithm for learning in d-dimensional (or infinite dimensional) balls. Given these two learners, we decompose the problem of learning a vector  $x_t$  in the problem of learning a direction and a magnitude. The regret of this procedure turns out to be just the sum of the regret of the two learners.

We can formalize this idea in the following Theorem.

#### Algorithm 9.3 Learning Magnitude and Direction Separately

**Require:** 1d Online learning algorithm  $A_{1d}$ , Online learning algorithm  $A_{B}$  with feasible set equal to the unit ball  $B \subset \mathbb{R}^d$  w.r.t.  $\|\cdot\|$ 

- 1: for t = 1 to T do
- Get point  $z_t \in \mathbb{R}$  from  $\mathcal{A}_{1d}$ 2:
- Get point  $\tilde{x}_t \in B$  from  $A_B$
- Play  $\boldsymbol{x}_t = z_t \tilde{\boldsymbol{x}}_t \in \mathbb{R}^d$
- pay  $\ell_t(\boldsymbol{x}_t)$  for  $\ell_t: \mathbb{R}^d \to \mathbb{R}$
- Set  $\boldsymbol{g}_t \in \partial \ell_t(\boldsymbol{x}_t)$
- Set  $s_t = \langle \boldsymbol{g}_t, \tilde{\boldsymbol{x}}_t \rangle$ Send  $\ell_t^{\mathcal{A}_{\mathrm{Id}}}(x) = s_t x$  as the t-th linear loss to  $\mathcal{A}_{\mathrm{Id}}$
- Send  $\ell_t^{\mathcal{A}_B}(x) = \langle g_t, x \rangle$  as the t-th linear loss to  $\mathcal{A}_B$
- 10: end for

**Theorem 9.16.** Denote by Regret $_T^{A_B}(u)$  the linear regret of algorithm  $A_B$  for any u in the unit ball w.r.t a norm  $\|\cdot\|$ , and  $\operatorname{Regret}_{T}^{\mathcal{A}_{Id}}(u)$  the linear regret of algorithm  $\mathcal{A}_{Id}$  for any competitor  $u\in\mathbb{R}$ . Then, for any  $u\neq 0\in\mathbb{R}^d$ , Algorithm 9.3 guarantees regret

$$\operatorname{Regret}_{T}(\boldsymbol{u}) = \sum_{t=1}^{T} \ell_{t}(\boldsymbol{x}_{t}) - \sum_{t=1}^{T} \ell_{t}(\boldsymbol{u}) \leq \sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{u} \rangle = \operatorname{Regret}_{T}^{\mathcal{A}_{Id}}(\|\boldsymbol{u}\|) + \|\boldsymbol{u}\| \operatorname{Regret}_{T}^{\mathcal{A}_{B}} \left(\frac{\boldsymbol{u}}{\|\boldsymbol{u}\|}\right),$$

and

$$\operatorname{Regret}_T(\mathbf{0}) \leq \operatorname{Regret}_T^{\mathcal{A}_{Id}}(0)$$
.

Further, the subgradients  $s_t$  sent to  $A_{Id}$  satisfy  $|s_t| \leq ||g_t||_{\star}$ .

*Proof.* First, observe that  $|s_t| \le \|g_t\|_\star \|\tilde{x}_t\| \le \|g_t\|_\star$  since  $\|\tilde{x}_t\| \le 1$  for all t. Now, assuming  $u \ne 0$  compute:

$$\begin{aligned} \operatorname{Regret}_{T}(\boldsymbol{u}) &= \sum_{t=1}^{T} \ell_{t}(\boldsymbol{x}_{t}) - \sum_{t=1}^{T} \ell_{t}(\boldsymbol{u}) \leq \sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{u} \rangle = \sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, z_{t} \tilde{\boldsymbol{x}}_{t} \rangle - \langle \boldsymbol{g}_{t}, \boldsymbol{u} \rangle \\ &= \sum_{t=1}^{T} \left( \langle \boldsymbol{g}_{t}, \tilde{\boldsymbol{x}}_{t} \rangle z_{t} - \langle \boldsymbol{g}_{t}, \tilde{\boldsymbol{x}}_{t} \rangle \|\boldsymbol{u}\| \right) + \sum_{t=1}^{T} \left( \langle \boldsymbol{g}_{t}, \tilde{\boldsymbol{x}}_{t} \rangle \|\boldsymbol{u}\| - \langle \boldsymbol{g}_{t}, \boldsymbol{u} \rangle \right) \\ &= \operatorname{Regret}_{T}^{\mathcal{A}_{\mathsf{Id}}}(\|\boldsymbol{u}\|) + \sum_{t=1}^{T} \left( \langle \boldsymbol{g}_{t}, \tilde{\boldsymbol{x}}_{t} \rangle \|\boldsymbol{u}\| - \langle \boldsymbol{g}_{t}, \boldsymbol{u} \rangle \right) \\ &= \operatorname{Regret}_{T}^{\mathcal{A}_{\mathsf{Id}}}(\|\boldsymbol{u}\|) + \|\boldsymbol{u}\| \sum_{t=1}^{T} \left( \langle \boldsymbol{g}_{t}, \tilde{\boldsymbol{x}}_{t} \rangle - \left\langle \boldsymbol{g}_{t}, \frac{\boldsymbol{u}}{\|\boldsymbol{u}\|} \right\rangle \right) \\ &= \operatorname{Regret}_{T}^{\mathcal{A}_{\mathsf{Id}}}(\|\boldsymbol{u}\|) + \|\boldsymbol{u}\| \operatorname{Regret}_{T}^{\mathcal{A}_{B}}\left( \frac{\boldsymbol{u}}{\|\boldsymbol{u}\|} \right). \end{aligned}$$

The case u = 0 follows similarly.

**Remark 9.17.** Note that the direction vector is not constrained to have norm equal to 1, that would be a non-convex constraint, yet this does not seem to affect the regret equality.

We will use this theorem in Section 10.4.

### 9.4 History Bits

The reduction from learning from  $\mathbb{R}^d_{\geq 0}$  to  $\Delta^{d-1}$  is a classic approach hidden in most of the learning with experts algorithms. Cesa-Bianchi and Lugosi [2006, Section 2.1] describes a similar version but through the formalism of potential functions, that does not result in a black-box reduction.

As far as I know, the idea of using a black-box reduction for constrained optimization does not appear in the offline and stochastic optimization literature. Cutkosky and Orabona [2018] proposed the first reduction from constrained OCO to unconstrained OCO described in Section 9.1.1. Cutkosky [2020a] proposed the third surrogate loss. Farina et al. [2019b] independently from the above work proved Theorem 9.12.

The Remark 9.8 is taken from the method in Mhammedi and Gatmiry [2023].

Regret Matching (RM) was proposed by Hart and Mas-Colell [2000] and Regret Matching+ (RM+) by Tammelin et al. [2015]. RM was developed to find correlated equilibria in two-player games and is commonly used to minimize regret over the simplex. RM+ is a modification of RM designed to accelerate convergence and used to effectively solve the game of Heads-up Limit Texas Hold'em poker [Bowling et al., 2015].

The observation that RM can be expressed as FTRL is due to Nicolò Cesa-Bianchi in an unpublished manuscript titled "The Joys of Regret Matching" dated October 14, 2015 (see Exercise 9.2). That result was shared with a number of people (including myself) and then later appeared in some papers too, unfortunately without proper credits. The observation that RM+ can be obtained by projected OGD is by Farina et al. [2021] and independently by Flaspohler et al. [2021].

RM and RM+ were extended to p-norms by Greenwald et al. [2006] and D'Orazio [2020], respectively. Tuning p with knowledge of d, one gets the optimal dependency in d but still without a learning rate nor a regularizer weight to tune. Later, Flaspohler et al. [2021] rediscovered both these results.

The setting of sleeping experts have been proposed by Blum [1997] and Freund et al. [1997]. The reduction in Section 9.2 is an extension of the one from Gaillard et al. [2014] that was designed to reducing the sleeping experts problem to the learning with experts problem rather than OLO in  $\mathbb{R}^d_{\geq 0}$ . I also added the minor improvement of removing the constant term from the surrogate losses. Such reduction is implicitly used by Luo and Schapire [2015] and by Jun et al. [2017a,b].

Theorem 9.16 is from Cutkosky and Orabona [2018]. Note that the original theorem is more general because it works even in Banach spaces.

#### 9.5 Exercises

**Problem 9.1.** Find a solution to the projection from  $\mathbb{R}^d$  to  $\Delta^{d-1}$  with respect to the  $L_1$  norm.

Problem 9.2. The Regret Matching algorithm predicts with

$$x_{t,i} = \frac{\max\left(\sum_{n=1}^{t-1} (g_{n,i} - \langle \boldsymbol{g}_n, \boldsymbol{x}_n \rangle), 0\right)}{\sum_{j=1}^{d} \max\left(\sum_{n=1}^{t-1} (g_{n,j} - \langle \boldsymbol{g}_n, \boldsymbol{x}_n \rangle), 0\right)}, i = 1, \dots, d.$$

Prove that it corresponds to FTRL with a squared  $L_2$  regularizer and  $\mathcal{V} = \mathbb{R}^d_{\geq 0}$  with projections onto  $\Delta^{d-1}$  with respect to the  $L_1$  norm. Then, prove a regret upper bound proportional to  $\sqrt{dT}$ . Hint: see Farina et al. [2021] and Flaspohler et al. [2021].

## Chapter 10

# Parameter-free Online Linear Optimization

In the previous sections, we have shown that Online Mirror Descent (OMD) and Follow-The-Regularized-Leader (FTRL) achieves a regret of  $\mathcal{O}(\sqrt{T})$  for convex Lipschitz losses. We have also shown that for bounded domains these bounds are optimal up to constant multiplicative factors. However, in the unbounded case the bounds we get are suboptimal w.r.t. the dependency on the competitor. More in particular, let's consider an example with Online Subgradient Descent with  $\mathcal{V}=\mathbb{R}^d$  over 1-Lipschitz losses and learning rate  $\eta=\frac{\alpha}{\sqrt{T}}$ . We get the following regret guarantee

$$\operatorname{Regret}_{T}(\boldsymbol{u}) = \sum_{t=1}^{T} \ell_{t}(\boldsymbol{x}_{t}) - \sum_{t=1}^{T} \ell_{t}(\boldsymbol{u}) \leq \frac{\|\boldsymbol{u}\|_{2}^{2}}{2\eta} + \frac{\eta T}{2} = \frac{1}{2}\sqrt{T}\left(\frac{\|\boldsymbol{u}\|_{2}^{2}}{\alpha} + \alpha\right), \ \forall \boldsymbol{u} \in \mathbb{R}^{d}.$$

So, in order to get the best possible guarantee, we should know  $\|u\|_2$  and set  $\alpha = \|u\|_2$ . As we said, this strategy does not work for a couple of reasons: i) u is not a fixed vector, rather the regret is a function of  $u \in \mathcal{V}$ ; ii) if we guessed any value of  $\|u\|_2$  the adversary could easily change the losses to make that value completely wrong.

Far from being a technicality, this is an important issue as shown in the next example.

**Example 10.1.** Consider that we want to use OSD with online-to-batch conversion to minimize a function that is 1-Lipschitz, whose minimizer is  $\mathbf{x}^*$ . The convergence rate will be proportional to  $(\frac{\|\mathbf{x}^*\|_2^2}{\alpha} + \alpha)\sqrt{T}$  using a learning rate of  $\eta = \frac{\alpha}{\sqrt{T}}$ . Consider the case that  $\|\mathbf{x}^*\|_2 = 100$ , specifying  $\alpha = 1$  will result in a convergence rate 100 times slower that specifying the optimal choice in hindsight  $\alpha = 100$ . Note that this is a real effect not an artifact of the proof. Indeed, it is intuitive that the optimal learning rate should be proportional to the distance between the initial point that algorithm picks and the optimal solution.

If we could tune the learning rate in the optimal way, we would get a regret of

$$\operatorname{Regret}_T(\boldsymbol{u}) \leq \|\boldsymbol{u}\|_2 \sqrt{T}, \forall \boldsymbol{u} \in \mathcal{V}$$
.

However, this is also impossible, because in Chapter 5 we proved a lower bound on the regret of  $\Omega(\|\boldsymbol{u}\|_2 \sqrt{T \ln \left(\sqrt{T} \|\boldsymbol{u}\|_2 + 1\right)} + 1)$ .

In the following, we will show that it is possible to reduce any Online Convex Optimization (OCO) game to betting on a non-stochastic coin. This will allow us to use a radically different way to design OCO algorithms that will enjoy the optimal regret and will not require any parameter (e.g., learning rates, regularization weights) to be tuned. We call these kind of algorithms *parameter-free*.

## 10.1 Coin-Betting Game

Imagine the following repeated game:

- Set the initial Wealth to  $\epsilon$ : Wealth<sub>0</sub> =  $\epsilon$ .
- In each round  $t = 1, \dots, T$ 
  - You bet  $|x_t|$  money on side of the coin equal to  $sign(x_t)$ . You cannot bet more money than what you currently have, hence  $|x_t| \leq Wealth_{t-1}$ .
  - The adversary reveals the outcome of the coin  $c_t \in \{-1, 1\}$ .
  - You gain money  $x_t c_t$ , that is Wealth<sub>t</sub> = Wealth<sub>t-1</sub> +  $c_t x_t = \epsilon + \sum_{i=1}^t c_i x_i$ .

Given that we cannot borrow money, we can codify the bets  $x_t$  as  $\beta_t$  Wealth<sub>t-1</sub>, with  $\beta_t \in [-1, 1]$ . So,  $|\beta_t|$  is the fraction of money to bet and sign( $\beta_t$ ) the side of the coin on which we bet.

The aim of the game is to make as much money as possible. As usual, given the adversarial nature of the game, we cannot hope to always win money. Instead, we try to gain as much money as the strategy that bets a fixed amount of money  $\beta^* \in [-1, 1]$  for the entire game.

Note that

Wealth<sub>t</sub> = Wealth<sub>t-1</sub> + 
$$c_t x_t$$
 = Wealth<sub>t-1</sub> +  $\beta_t$  Wealth<sub>t-1</sub>  $c_t$  = Wealth<sub>t-1</sub>  $(1 + \beta_t c_t) = \epsilon \prod_{i=1}^{t-1} (1 + \beta_i c_i)$ .

So, given the multiplicative nature of the wealth, it is also useful to take the logarithm of the ratio of the wealth of the algorithm and wealth of the optimal betting fraction. Hence, we want to minimize the following regret

$$\ln \max_{\beta \in [-1,1]} \epsilon \prod_{t=1}^{T} (1 + \beta c_t) - \ln \text{Wealth}_T = \ln \max_{\beta \in [-1,1]} \epsilon \prod_{t=1}^{T} (1 + \beta c_t) - \ln \left( \epsilon \prod_{t=1}^{T} (1 + \beta_t c_t) \right)$$

$$= \max_{\beta \in [-1,1]} \sum_{t=1}^{T} \ln(1 + \beta c_t) - \sum_{t=1}^{T} \ln(1 + \beta_t c_t).$$

In words, this is nothing else than the regret of an OCO game where the losses are  $\ell_t(x) = -\ln(1 + xc_t)$  and  $\mathcal{V} = [-1, 1]$ . We can also extend a bit the formulation allowing "continuous coins", where  $c_t \in [-1, 1]$  rather than in  $\{-1, 1\}$ .

Remark 10.2. Note that the constraint to bet a fraction between -1 and 1 is not strictly necessary. We could allow the algorithm to bet more money than what it currently has, lending it some money in each round. However, the restriction makes the analysis easier because it allows the transformation above into an OCO problem, using the non-negativity of  $1 + \beta_t c_t$ .

We could just use OMD or FTRL, taking special care of the non-Lipschitzness of the functions, but it turns out that there exists a better strategy specifically for this problem. There exists a very simple strategy to solve the coinbetting game above, that is called **Krichevsky-Trofimov** (**KT**) **bettor**. It simply says that on each time step t you bet  $\beta_t = \frac{\sum_{i=1}^{t-1} c_i}{t}$ . So, the algorithm is the following one.

#### Algorithm 10.1 Krichevsky-Trofimov Bettor

**Require:** Initial money Wealth<sub>0</sub> =  $\epsilon > 0$ 

- 1: for t=1 to T do
- 2: Calculate the betting fraction  $\beta_t = \frac{\sum_{i=1}^{t-1} c_i}{t}$
- 3: Bet  $x_t = \beta_t \operatorname{Wealth}_{t-1}$ , that is  $|x_t|$  money on the side  $\operatorname{sign}(x_t) = \operatorname{sign}(\beta_t)$
- 4: Receive the coin outcome  $c_t \in [-1, 1]$
- 5: Win/lose  $x_t c_t$ , that is Wealth<sub>t</sub> = Wealth<sub>t-1</sub> +  $c_t x_t$
- 6: end for

For it, we can prove the following theorem.

**Theorem 10.3** ([Cesa-Bianchi and Lugosi, 2006, Theorem 9.4]). Let  $c_t \in \{-1, 1\}$  for t = 1, ..., T. Then, the KT bettor in Algorithm 10.1 guarantees

ln Wealth<sub>T</sub> 
$$\geq \ln \max_{\beta \in [-1,1]} \prod_{t=1}^{T} (1 + \beta c_t) - \frac{1}{2} \ln T - K,$$

where K is a universal constant.

Note that if the outcomes of the coin are skewed towards one side, the optimal betting fraction will gain an exponential amount of money, as proved in the next Lemma.

**Lemma 10.4.** Let  $c_t \in \{-1, 1\}, t = 1, ..., T$ . Then, we have

$$\max_{\beta \in [-1,1]} \exp \left( \sum_{t=1}^T \ln(1+\beta c_t) \right) \ge \exp \left( \sum_{t=1}^T \frac{\left(\sum_{t=1}^T c_t\right)^2}{4T} \right) .$$

Proof.

$$\max_{\beta \in [-1,1]} \exp\left(\sum_{t=1}^{T} \ln(1+\beta c_t)\right) \ge \max_{\beta \in [-1/2,1/2]} \exp\left(\sum_{t=1}^{T} \ln(1+\beta c_t)\right) \ge \max_{\beta \in [-1/2,1/2]} \exp\left(\beta \sum_{t=1}^{T} c_t - \beta^2 \sum_{t=1}^{T} c_t^2\right) \\
= \max_{\beta \in [-1/2,1/2]} \exp\left(\beta \sum_{t=1}^{T} c_t - \beta^2 T\right) = \exp\left(\frac{\left(\sum_{t=1}^{T} c_t\right)^2}{4T}\right).$$

where we used the elementary inequality  $\ln(1+x) \ge x - x^2$  for  $x \in [-1/2, 1/2]$ .

Hence, KT guarantees an exponential amount of money, paying only a  $\sqrt{T}$  penalty. It is possible to prove that the guarantee above for the KT algorithm is optimal to constant additive factors. Moreover, observe that the KT strategy does not require any parameter to be set: no learning rates, nor regularizer. That is, KT is *parameter-free*.

Also, we can extend the guarantee of the KT algorithm to the case in which the coins are "continuous", that is  $c_t \in [-1, 1]$ . We have the following Theorem.

**Theorem 10.5** ([Orabona and Pál, 2016, Lemma 14]). Let  $c_t \in [-1, 1]$  for t = 1, ..., T. Then, the KT bettor in Algorithm 10.1 guarantees

$$\ln \operatorname{Wealth}_{T} \ge \sum_{t=1}^{T} \frac{\left(\sum_{t=1}^{T} c_{t}\right)^{2}}{4T} - \frac{1}{2} \ln T - K,$$

where K is a universal constant.

So, we have introduced the coin-betting game, extended it to continuous coins and presented a simple and optimal parameter-free strategy. In the next Section, we show how to use the KT bettor as a parameter-free 1-d OCO algorithm!

### 10.2 Parameter-free 1d OCO through Coin-Betting

So, Theorem 10.3 tells us that we can win almost as much money as a strategy betting the optimal fixed fraction of money at each step. We only pay a logarithmic price in the log wealth, that corresponds to a  $\frac{1}{\sqrt{T}}$  term in the actual wealth

Now, let's see why this problem is interesting in OCO. It turns out that solving the coin-betting game with continuous coins is equivalent to solving a 1-dimensional unconstrained online linear optimization problem. That is, a

coin-betting algorithm is equivalent to design an online learning algorithm that produces a sequences of  $x_t \in \mathbb{R}$  that minimize the 1-dimensional regret with linear losses:

Regret<sub>T</sub>(u) := 
$$\sum_{t=1}^{T} g_t x_t - \sum_{t=1}^{T} g_t u$$
,

where the  $g_t$  are adversarial and bounded. Without loss of generality, we will assume  $g_t \in [-1, 1]$ . Also, remembering that OCO games can be reduced to Online Linear Optimization (OLO) games, such reduction would effectively reduces OCO to coin-betting! Moreover, through online-to-batch conversion, any stochastic 1-d problem could be reduced to a coin-betting game!

The key theorem that allows the conversion between OLO and coin-betting is the following one.

**Theorem 10.6** (Regret/Reward duality). Let  $\phi: \mathbb{R}^d \to (-\infty, +\infty]$  be a proper closed convex function and let  $\phi^*: \mathbb{R}^d \to (-\infty, +\infty]$  be its Fenchel conjugate. Consider two arbitrary sequences  $\mathbf{x}_1, \mathbf{x}_2, \dots, \mathbf{x}_T \in \mathbb{R}^d$  and  $\mathbf{g}_1, \dots, \mathbf{g}_T \in \mathbb{R}^d$ . Then, an online algorithm that generates guarantees

$$-\sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} \rangle \geq \phi \left( -\sum_{t=1}^{T} \boldsymbol{g}_{t} \right),$$

if and only if it guarantees

$$\underbrace{\sum_{t=1}^{T} \langle oldsymbol{g}_t, oldsymbol{x}_t - oldsymbol{u} 
angle}_{ ext{Regret}_T(oldsymbol{u})} \leq \phi^{\star}(oldsymbol{u}), \ orall oldsymbol{u} \in \mathbb{R}^d \ .$$

*Proof.* Let's prove the left to right implication. For any  $u \in \mathbb{R}^d$ , we have

$$\begin{aligned} \operatorname{Regret}_{T}(\boldsymbol{u}) &= \sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{u} \rangle \leq -\sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{u} \rangle - \phi \left( -\sum_{t=1}^{T} \boldsymbol{g}_{t} \right) \\ &\leq \sup_{\boldsymbol{\theta} \in \mathbb{R}^{d}} \langle \boldsymbol{\theta}, \boldsymbol{u} \rangle - \phi \left( \boldsymbol{\theta} \right) = \phi^{\star} \left( \boldsymbol{u} \right) \; . \end{aligned}$$

For the other implication, we have

$$-\sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} \rangle = -\sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{u} \rangle - \sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{u} \rangle = \sup_{\boldsymbol{u} \in \mathbb{R}^{d}} -\sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{u} \rangle - \sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{u} \rangle$$

$$\geq \sup_{\boldsymbol{u} \in \mathbb{R}^{d}} -\sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{u} \rangle - \phi^{\star}(\boldsymbol{u}) = \phi\left(-\sum_{t=1}^{T} \boldsymbol{g}_{t}\right).$$

To make sense of the above theorem, assume that we are considering a 1-d problem and  $g_t \in [-1,1]$ . Then, guaranteeing a lower bound to the wealth

$$\epsilon - \sum_{t=1}^{T} \langle oldsymbol{g}_t, oldsymbol{x}_t 
angle$$

can be done through a betting strategy that bets  $x_t$  money on the coins  $c_t = -g_t$ . So, the theorem implies that proving a lower bound for the wealth in a coin-betting game implies a regret upper bound for the corresponding 1-dimensional OLO game. However, proving a reward lower bound is easier because it doesn't depend on the competitor u. Indeed, not knowing the norm of the competitor is exactly the reason why tuning the learning rates in OMD is hard!

This consideration immediately gives us the conversion between 1-d OLO and coin-betting: the outcome of the coin is the negative of the subgradient of the losses on the current prediction. Indeed, setting  $c_t = -g_t$ , we have that a coin-betting algorithm that bets  $x_t$  would give us

Wealth<sub>T</sub> = 
$$\epsilon + \sum_{t=1}^{T} x_t c_t = \epsilon - \sum_{t=1}^{T} x_t g_t$$
.

So, a lower bound on the wealth corresponds to a lower bound that can be used in Theorem 10.6. To obtain a regret guarantee, we only need to calculate the Fenchel conjugate of the reward function, assuming it can be expressed as a function of  $\sum_{t=1}^{T} c_t$ .

The last step is to reduce 1-d OCO to 1-d OLO. But, this is an easy step that we have done many times. Indeed, we have

$$Regret_{T}(u) = \sum_{t=1}^{T} \ell_{t}(x_{t}) - \sum_{t=1}^{T} \ell_{t}(u) \le \sum_{t=1}^{T} x_{t}g_{t} - \sum_{t=1}^{T} g_{t}u,$$

where  $g_t \in \partial \ell_t(x_t)$ .

So, to summarize, the Fenchel conjugate of the wealth lower bound for the coin-betting game becomes the regret guarantee for the OCO game. In the next section, we specialize all these considerations to the KT algorithm.

#### 10.2.1 KT as a 1d Online Convex Optimization Algorithm

Here, we want to use the considerations in the above section to use KT as a parameter-free 1-d OCO algorithm. First, let's see what such algorithm looks like. KT bets  $x_t = \beta_t$  Wealth $_{t-1}$ , starting with  $\epsilon$  money. Now, set  $c_t = -g_t$  where  $g_t \in \partial \ell_t(x_t)$  and assume the losses  $\ell_t$  1-Lipschitz. So, we get

$$x_t = -\frac{\sum_{i=1}^{t-1} g_i}{t} \left( \epsilon - \sum_{i=1}^{t-1} g_i x_i \right).$$

The pseudo-code is in Algorithm 10.2.

#### Algorithm 10.2 Krichevsky-Trofimov OCO Algorithm

**Require:**  $\epsilon > 0$  (any number between 1 and  $\sqrt{T}$ )

- 1: for t=1 to T do
- 2: Predict  $x_t = -\frac{\sum_{i=1}^{t-1} g_i}{t} \left( \epsilon \sum_{i=1}^{t-1} g_i x_i \right) \in \mathbb{R}$
- 3: Receive loss  $\ell_t : \mathbb{R} \to \mathbb{R}$  and pay  $\ell_t(x_t)$
- 4: Set  $g_t \in \partial \ell_t(x_t)$
- 5: end for

Let's now see what kind of regret we get. From Theorem 10.5, we have that the KT bettor guarantees the following lower bound on the wealth when used with  $c_t = -g_t$ :

$$\epsilon - \sum_{t=1}^{T} x_t g_t \ge \frac{\epsilon}{K\sqrt{T}} \exp\left(\frac{(\sum_{t=1}^{T} g_t)^2}{4T}\right).$$

So, we found the function  $\phi$ , we just need  $\phi^*$  or an upper bound to it, that can be found with the following Lemma.

**Lemma 10.7.** Define  $f(x) = \beta \exp \frac{x^2}{2\alpha}$ , for  $\alpha, \beta > 0$ ,  $x \ge 0$ . Then

$$f^{\star}(y) = |y| \sqrt{\alpha W\left(\frac{\alpha y^2}{\beta^2}\right)} - \beta \exp\left(\frac{W\left(\frac{\alpha y^2}{\beta^2}\right)}{2}\right) \le |y| \sqrt{\alpha W\left(\frac{\alpha y^2}{\beta^2}\right)} - \beta \le |y| \sqrt{\alpha \ln\left(1 + \frac{\alpha y^2}{\beta^2}\right)} - \beta,$$

where W is the Lambert function, i.e.,  $W: \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$  satisfies  $x = W(x) \exp(W(x))$ .

*Proof.* From the definition of Fenchel dual, we have

$$f^*(y) = \max_{x} xy - f(x) = \max_{x} xy - \beta \exp \frac{x^2}{2\alpha} \le x^*y - \beta,$$

where  $x^* = \operatorname{argmax}_x x \, y - f(x)$ . We now use the fact that  $x^*$  satisfies  $y = f'(x^*)$ , to have  $x^* = \operatorname{sign}(y) \sqrt{\alpha W\left(\frac{\alpha y^2}{\beta^2}\right)}$ , where  $W(\cdot)$  is the Lambert function. Using Lemma C.3 in the Appendix, we obtain the stated bound.

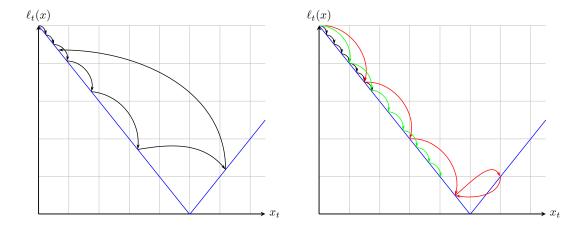

Figure 10.1: Behaviour of KT (left) and online gradient descent with various learning rates and same number of steps (right) when  $\ell_t(x) = |x - 10|$  for all t.

So, the regret guarantee of KT used a 1d OLO algorithm is upper bounded by

$$\operatorname{Regret}_{T}(u) = \sum_{t=1}^{T} \ell_{t}(x_{t}) - \sum_{t=1}^{T} \ell_{t}(u) \leq |u| \sqrt{4T \ln \left(\frac{\sqrt{2}|u|KT}{\epsilon} + 1\right)} + \epsilon, \ \forall u \in \mathbb{R},$$

where the only assumption was that the first derivatives (or sub-derivatives) of  $\ell_t$  are bounded in absolute value by 1. Also, it is important to note that any setting of  $\epsilon$  in  $[1, \sqrt{T}]$  would not change the asymptotic rate.

To better appreciate this regret, compare this bound to the one of OMD with learning rate  $\eta = \frac{\alpha}{\sqrt{T}}$ :

$$\operatorname{Regret}_{T}(u) = \sum_{t=1}^{T} \ell_{t}(x_{t}) - \sum_{t=1}^{T} \ell_{t}(u) \leq \frac{1}{2} \left( \frac{u^{2}}{\alpha} + \alpha \right) \sqrt{T}, \ \forall u \in \mathbb{R}.$$

Hence, the coin-betting approach allows to get almost the optimal bound, without having to guess the correct learning rate! The price that we pay for this parameter-freeness is the log factor, that is optimal from our lower bound.

It is interesting also to look at what the algorithm would do on an easy problem, where  $\ell_t(x) = |x - 10|$ . In Figure 10.1, we show the different predictions that the KT algorithm and online subgradient descent (OSD) would do. Note how the convergence rate of OSD critically depends on the learning rate: too big will not give convergence and too small will make slow down the convergence. On the other hand, KT will go *exponentially fast* towards the minimum and then it will automatically backtrack. This exponential growth effectively works like a line search procedure that allows to get the optimal regret without tuning learning rates. Later in the iterations, KT will oscillate around the minimum, *automatically shrinking its steps*, *without any parameter to tune*. Of course, this is a simplified example. In a truly OCO game, the losses are different at each time step and the intuition behind the algorithm becomes more difficult. Yet, the optimality of the regret assures us that the KT strategy is the right strategy.

Next, we will see that we can also reduce OCO in  $\mathbb{R}^d$  and learning with experts to coin-betting games.

#### 10.3 Coordinate-wise Parameter-free OCO

We have already seen that it is always possible to decompose an OCO problem over the coordinates and use a different 1-dimensional Online Linear Optimization algorithm on each coordinate. In particular, we saw that

$$\operatorname{Regret}_{T}(\boldsymbol{u}) = \sum_{t=1}^{T} \ell_{t}(\boldsymbol{x}_{t}) - \sum_{t=1}^{T} \ell_{t}(\boldsymbol{u}) \leq \sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} \rangle - \sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{u} \rangle$$
$$= \sum_{t=1}^{T} \sum_{i=1}^{d} g_{t,i}(x_{t,i} - u_{i}) = \sum_{i=1}^{d} \sum_{t=1}^{T} g_{t,i}(x_{t,i} - u_{i}),$$

where the  $\sum_{t=1}^{T} g_{t,i}(x_{t,i} - u_i)$  is exactly the regret w.r.t. the linear losses constructed by the coordinate i of the subgradient.

Hence, if we have a 1-dimensional OLO algorithm, we can d copies of it, each one fed with the coordinate i of the subgradient. In particular, we might think to use the KT algorithm over each coordinate. The pseudo-code of this procedure is in Algorithm 10.3.

#### Algorithm 10.3 OCO with Coordinate-Wise Krichevsky-Trofimov

**Require:**  $\epsilon > 0$ 

- 1: for t=1 to T do
- 2: Output  $x_t$  whose coordinates are  $x_{t,i} = -\frac{\sum_{j=1}^{t-1} g_{j,i}}{t} \left(\epsilon \sum_{j=1}^{t-1} g_{j,i} x_{j,i}\right)$  for  $i = 1, \ldots, d$
- 3: Pay  $\ell_t(\boldsymbol{x}_t)$  for  $\ell_t: \mathbb{R}^d \to \mathbb{R}$
- 4: Set  $\boldsymbol{g}_t \in \partial \ell_t(\boldsymbol{x}_t)$
- 5: end for

The regret bound we get is immediate: We just have to sum the regret over the coordinates.

**Theorem 10.8.** With the notation in Algorithm 10.3, assume that  $\|g_t\|_{\infty} \leq 1$ . Then,  $\forall u \in \mathbb{R}^d$ , the following regret bounds hold

$$\sum_{t=1}^{T} (\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) \leq \sum_{i=1}^{d} |u_i| \sqrt{4T \ln\left(1 + \frac{\sqrt{2}u_i^2 KT}{\epsilon}\right)} + d\epsilon \leq \|\boldsymbol{u}\|_1 \sqrt{4T \ln\left(1 + \frac{\sqrt{2}\|\boldsymbol{u}\|_{\infty}^2 KT}{\epsilon}\right)} + d\epsilon,$$

where K is a universal constant.

The Theorem above suggests that in high dimensional settings  $\epsilon$  should be proportional to  $\frac{1}{d}$ .

## **10.4** Parameter-free in Any Norm

The above reductions works only with in a finite dimensional space. Moreover, it gives a dependency on the competitor w.r.t. the  $L_1$  norm that might be undesirable. So, here we use the magnitude/direction reduction from Section 9.3.

We can instantiate the above theorem using the KT betting algorithm for the 1d learner and OMD for the direction learner. Observe that in order to have the coin outcomes in [-1,1], we need to divide the losses by the Lipschitz constant. More in details, let  $\mathcal{A}_B$  be OSD with  $\mathcal{V}=\{\boldsymbol{x}\in\mathbb{R}^d:\|\boldsymbol{x}\|_2\leq 1\}$ ,  $\boldsymbol{x}_1=\boldsymbol{0}$ , and learning rate  $\eta_t=\frac{\sqrt{2}}{2\sqrt{t}}$ . Let  $\mathcal{A}_{1d}$  the KT algorithm for 1-dimensional OCO with  $\epsilon=1$ . Assume the loss functions are 1-Lipschitz w.r.t. the  $\|\cdot\|_2$ . Then, using the construction in Algorithm 9.3, we have

$$\operatorname{Regret}_{T}(\boldsymbol{u}) \leq \mathcal{O}\left(\left(\|\boldsymbol{u}\|_{2}\sqrt{\ln(\|\boldsymbol{u}\|_{2}T+1)} + \|\boldsymbol{u}\|_{2}\right)\sqrt{T} + 1\right), \ \forall \boldsymbol{u} \in \mathbb{R}^{d}.$$
(10.1)

Using an online-to-batch conversion, this algorithm is a stochastic gradient descent procedure without learning rates to tune.

To better appreciate this kind of guarantee, let's take a look at the one of FTRL (remember that OSD can be used in unbounded domains only with constant learning rates). With the regularizer  $\psi_t(x) = \frac{\sqrt{t}}{2\alpha} ||x||_2$  and 1-Lipschitz losses we get a regret of

$$\operatorname{Regret}_{T}(\boldsymbol{u}) \leq \sqrt{T} \left( \frac{\|\boldsymbol{u}\|_{2}^{2}}{2\alpha} + \alpha \right).$$

So, to get the right dependency on  $\|u\|_2$  we need to tune  $\alpha$ , but we saw this is impossible. On the other hand, the regret in (10.1) suffers from a logarithmic factor, that is the price to pay not to have to tune parameters.

In the same way, we can even have a parameter-free regret bound for  $L_p$  norms. Let  $\mathcal{A}_B$  be OMD with  $\mathcal{V}=\{\boldsymbol{x}\in\mathbb{R}^d: \|\boldsymbol{x}\|_p\leq 1\}$  and learning rate  $\eta_t=\frac{\sqrt{2(p-1)}D}{2\sqrt{t}}$ . Let  $\mathcal{A}_{1d}$  the KT algorithm for 1-dimensional OCO with  $\epsilon=1$ . Assume the loss functions are 1-Lipschitz w.r.t. the  $\|\cdot\|_q$ . Then, using the construction in Algorithm 9.3, we have

$$\operatorname{Regret}_{T}(\boldsymbol{u}) \leq \mathcal{O}\left(\left(\|\boldsymbol{u}\|_{p}\sqrt{\ln(\|\boldsymbol{u}\|_{p}T+1)} + \frac{\|\boldsymbol{u}\|_{p}}{\sqrt{p-1}}\right)\sqrt{T} + 1\right), \ \forall \boldsymbol{u} \in \mathbb{R}^{d}.$$

If we want to measure the competitor w.r.t the  $L_1$  norm, we have to use the same method we saw for OMD in Section 6.7: Set  $q=2\ln d$  and p such that 1/p+1/q=1. Now, assuming that  $\|\boldsymbol{g}_t\|_{\infty}\leq 1$ , we have that  $\|\boldsymbol{g}_t\|_q\leq d^{1/q}$ . Hence, we have to divide all the losses by  $d^{1/q}$  and, for all  $\boldsymbol{u}\in\mathbb{R}^d$ , we obtain

$$d^{-1/q} \sum_{t=1}^{T} (\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) \le \mathcal{O}\left(\left(\|\boldsymbol{u}\|_p \sqrt{\ln(\|\boldsymbol{u}\|_p T + 1)} + \|\boldsymbol{u}\|_p \sqrt{q - 1}\right) \sqrt{T} + 1\right)$$

$$\le \mathcal{O}\left(\left(\|\boldsymbol{u}\|_1 \sqrt{\ln(\|\boldsymbol{u}\|_1 T + 1)} + \|\boldsymbol{u}\|_1 \sqrt{\ln d}\right) \sqrt{T} + 1\right).$$

Note that the regret against u = 0 of the parameter-free construction is *constant*. It is important to understand that there is nothing special in the origin in the unconstrained setting: We could translate the prediction by any offset and get a guarantee that treats the offset as the point with constant regret. This is shown in the next Proposition.

**Proposition 10.9.** Let A an OLO algorithm that predicts  $\mathbf{x}_t$  and guarantees linear regret  $\operatorname{Regret}_T^{OLO}(\mathbf{u})$  for any  $\mathbf{u} \in \mathbb{R}^d$ . We have that the regret of the predictions  $\hat{\mathbf{x}}_t = \mathbf{x}_t + \mathbf{x}_0$  for OCO is

$$\sum_{t=1}^T \ell_t(\hat{\boldsymbol{x}}_t) - \sum_{t=1}^T \ell_t(\boldsymbol{u}) \le \sum_{t=1}^T \langle \boldsymbol{g}_t, \boldsymbol{x}_t + \boldsymbol{x}_0 - \boldsymbol{u} \rangle = \operatorname{Regret}_T^{OLO}(\boldsymbol{u} - \boldsymbol{x}_0) \ .$$

## 10.5 Combining Online Convex Optimization Algorithms

Finally, we now show a useful application of the parameter-free OCO algorithms property to have a constant regret against u = 0.

**Theorem 10.10.** Let  $A_1$  and  $A_2$  two OLO algorithms that produces the predictions  $x_{t,1}$  and  $x_{t,2}$  respectively. Then, predicting with  $x_t = x_{t,1} + x_{t,2}$ , we have for any  $u \in \mathbb{R}^d$ 

$$\sum_{t=1}^{T} \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle - \sum_{t=1}^{T} \langle \boldsymbol{g}_t, \boldsymbol{u} \rangle = \min_{\boldsymbol{u} = \boldsymbol{u}_1 + \boldsymbol{u}_2} \operatorname{Regret}_T^{\mathcal{A}_1}(\boldsymbol{u}_1) + \operatorname{Regret}_T^{\mathcal{A}_2}(\boldsymbol{u}_2) .$$

Moreover, if both algorithm guarantee a constant regret of  $\epsilon$  against u=0, we have for any  $u\in\mathbb{R}^d$ 

$$\sum_{t=1}^{T} \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle - \sum_{t=1}^{T} \langle \boldsymbol{g}_t, \boldsymbol{u} \rangle \leq \epsilon + \min \left( \text{Regret}_T^{\mathcal{A}_1}(\boldsymbol{u}), \text{Regret}_T^{\mathcal{A}_2}(\boldsymbol{u}) \right) \ .$$

*Proof.* Set  $u_1 + u_2 = u$ . Then,

$$\sum_{t=1}^T \langle oldsymbol{g}_t, oldsymbol{x}_t 
angle - \sum_{t=1}^T \langle oldsymbol{g}_t, oldsymbol{u} 
angle = \sum_{t=1}^T \langle oldsymbol{g}_t, oldsymbol{x}_{t,1} 
angle - \sum_{t=1}^T \langle oldsymbol{g}_t, oldsymbol{u}_1 
angle + \sum_{t=1}^T \langle oldsymbol{g}_t, oldsymbol{x}_{t,2} 
angle - \sum_{t=1}^T \langle oldsymbol{g}_t, oldsymbol{u}_2 
angle \ .$$

In words, the above theorem allows us to combine online learning algorithm. If the algorithms we combine have constant regret against the null competitor, then we always get the best of the two guarantees.

**Example 10.11.** We can combine two parameter-free OCO algorithms, one that gives a bound that depends on the  $L_2$  norm of the competitor and subgradients and another one specialized to the  $L_1/L_\infty$  norm of competitor/subgradients. The above theorem assures us that we will also get the best guarantee between the two, paying only an additive constant factor in the regret.

Of course, upper bounding the OCO regret with the linear regret, the above theorem also upper bounds the OCO regret.

### 10.6 Reduction to Learning with Experts

In this section, we consider again the learning with expert advice setting from 6.8. First, remember that the regret we got from OMD (and similarly for FTRL) is

$$\operatorname{Regret}_T(\boldsymbol{u}) \leq \mathcal{O}\left(\frac{\operatorname{KL}(\boldsymbol{u};\boldsymbol{\pi})}{\eta} + \eta T\right),$$

where  $\pi$  is the prior distribution on the experts and  $KL(\cdot;\cdot)$  is the KL-divergence. As we reasoned in the OCO case, in order to set the learning rate we should know the value of  $KL(u;\pi)$ . If we could set  $\eta$  to  $\sqrt{\frac{KL(u;\pi)}{T}}$ , we would obtain a regret of  $\sqrt{T\ KL(u;\pi)}$ . However, given the adversarial nature of the game, this is impossible. So, as we did in the OCO case, we will show that even this problem can be reduced to betting on a continuous coin, obtaining optimal regret guarantees with a parameter-free algorithm.

**Remark 10.12.** There exists a different notion of regret for learning with experts. Order the cumulative losses of all actions from lowest to highest and define the  $\epsilon$ -quantile regret to be the difference between the cumulative loss of the learner and the  $\lceil \epsilon d \rceil$ -th element in the sorted list. In formulas

$$\operatorname{Regret}_T(\epsilon) = \sum_{t=1}^T \langle \boldsymbol{g}_t, \boldsymbol{p}_t \rangle - \sum_{t=1}^T g_{t, i_\epsilon},$$

where  $\epsilon \in [1/d, 1]$  and  $i_{\epsilon}$  is the  $[\epsilon d]$ -th best performing action.

This definition makes sense when the number of actions is very large and there are many of them that are close to the optimal one. Note the task of guaranteeing a small regret becomes easier with increasing  $\epsilon$ . So, we would like to design an algorithm whose regret is inversely proportional to  $\epsilon$  and it also does not depend on d in any way.

We now show that a regret that depends on the KL divergence between a generic competitor  $\mathbf{u}$  and  $\mathbf{\pi}$  implies such regret guarantee. Define  $\mathbf{u}_{\epsilon}$  as the vector that has the coordinates corresponding to the best  $\lceil \epsilon d \rceil$  experts equal to  $\frac{1}{\lceil \epsilon d \rceil}$  and 0 in the other coordinates. Also, assume to have an algorithm that guarantees an upper bound  $\mathrm{Regret}_T(\mathbf{u})$  equal to  $F_T(\mathrm{KL}(\mathbf{u};\mathbf{\pi}))$  for a sequence of losses  $\mathbf{g}_t \in \mathbb{R}^d$ , where F is a non-decreasing function. Then, setting  $\mathbf{\pi} = \lceil 1/d, \ldots, 1/d \rceil$ , we have

$$\operatorname{Regret}_T(\epsilon) = \sum_{t=1}^T \langle \boldsymbol{g}_t, \boldsymbol{p}_t \rangle - \sum_{t=1}^T g_{t,i_\epsilon} \leq \sum_{t=1}^T \langle \boldsymbol{g}_t, \boldsymbol{p}_t - \boldsymbol{u}_\epsilon \rangle \leq F_T(KL(\boldsymbol{u}_\epsilon; \boldsymbol{\pi})) = F_T\left(\ln \frac{d}{\lceil \epsilon d \rceil}\right) \leq F_T\left(\ln \frac{1}{\epsilon}\right),$$

where in the first inequality we used the fact that the average of a set of numbers is smaller than the biggest number in the set.

First, let's introduce some notation. Let  $d \geq 2$  be the number of experts and  $\Delta^{d-1}$  be the probability simplex. Let  $\pi = [\pi_1, \pi_2, \dots, \pi_d] \in \Delta^{d-1}$  be any *prior* distribution. Let  $\mathcal A$  be a coin-betting algorithm. We will instantiate d copies of  $\mathcal A$ , each of them with initial wealth  $\pi_i$  for  $i=1,\dots,d$ .

Consider any round t. Let  $x_{t,i} \in \mathbb{R}$  be the bet of the i-th copy of A. The learning with expert advice algorithm computes  $\widehat{p}_t = [\widehat{p}_{t,1}, \widehat{p}_{t,2}, \dots, \widehat{p}_{t,d}] \in \mathbb{R}^d_{>0}$  as

$$\widehat{p}_{t,i} = \max(x_{t,i}, 0). \tag{10.2}$$

Then, the learning with expert advice algorithm predicts  $p_t = [p_{t,1}, p_{t,2}, \dots, p_{t,d}] \in \Delta^{d-1}$  as

$$\boldsymbol{p}_{t} = \begin{cases} \frac{\widehat{\boldsymbol{p}}_{t}}{\|\widehat{\boldsymbol{p}}_{t}\|_{1}}, & \text{if } \widehat{\boldsymbol{p}}_{t} \neq \boldsymbol{0}, \\ \boldsymbol{\pi}, & \text{otherwise} \end{cases}$$
(10.3)

After the prediction, the algorithm receives the vector of the losses for each expert  $\mathbf{g}_t = [g_{t,1}, g_{t,2}, \dots, g_{t,d}] \in [0,1]^d$ . From these losses, we construct the outcome of the continuous coin  $c_{t,i} \in [-1,1]$  for the i-th copy of betting algorithm  $\mathcal{A}$ , defined as

$$c_{t,i} = \begin{cases} \langle \boldsymbol{g}_t, \boldsymbol{p}_t \rangle - g_{t,i} & \text{if } x_{t,i} > 0, \\ \max(\langle \boldsymbol{g}_t, \boldsymbol{p}_t \rangle - g_{t,i}, 0) & \text{if } x_{t,i} \le 0. \end{cases}$$

$$(10.4)$$

The construction above defines a learning with expert advice algorithm defined by the predictions  $p_t$ , based on the algorithm A. We can prove the following regret bound for it.

**Theorem 10.13** (Regret Bound for Experts). Let A be a coin-betting algorithm that guarantees a wealth after t rounds with initial money equal to I of  $\exp(f_t(\sum_{i=1}^t c_t'))$  for any sequence of continuous coin outcomes  $c_1', \ldots, c_t' \in [-1, 1]$ . Then, the regret of the learning with expert advice algorithm with prior  $\pi \in \Delta^{d-1}$  that predicts at each round with  $p_t$  in (10.3) satisfies

$$\forall T \geq 0, \quad \forall \boldsymbol{u} \in \Delta^{d-1}, \qquad \qquad \operatorname{Regret}_T(\boldsymbol{u}) = \sum_{t=1}^T \langle \boldsymbol{g}_t, \boldsymbol{p}_t - \boldsymbol{u} \rangle \leq h\left(\operatorname{KL}(\boldsymbol{u}; \boldsymbol{\pi})\right),$$

for any  $h: \mathbb{R} \to \mathbb{R}$  concave and non-decreasing such that  $x \leq h(f_T(x))$ .

*Proof.* We first prove that  $\langle c_t, x_t \rangle < 0$ . Indeed,

$$\langle \boldsymbol{c}_{t}, \boldsymbol{x}_{t} \rangle = \sum_{i=1}^{d} c_{t,i} x_{t,i} = \sum_{i: x_{t,i} > 0} \max(x_{t,i}, 0) (\langle \boldsymbol{g}_{t}, \boldsymbol{p}_{t} \rangle - g_{t,i}) + \sum_{i: x_{t,i} \leq 0} x_{t,i} \max(\langle \boldsymbol{g}_{t}, \boldsymbol{p}_{t} \rangle - g_{t,i}, 0)$$

$$= \|\widehat{\boldsymbol{p}}_{t}\|_{1} \sum_{i=1}^{d} p_{t,i} (\langle \boldsymbol{g}_{t}, \boldsymbol{p}_{t} \rangle - g_{t,i}) + \sum_{i: x_{t,i} \leq 0} x_{t,i} \max(\langle \boldsymbol{g}_{t}, \boldsymbol{p}_{t} \rangle - g_{t,i}, 0)$$

$$= 0 + \sum_{i: x_{t,i} \leq 0} x_{t,i} \max(\langle \boldsymbol{g}_{t}, \boldsymbol{p}_{t} \rangle - g_{t,i}, 0) \leq 0.$$

The first equality follows from definition of  $c_{t,i}$ . To see the second equality, consider two cases: If  $x_{t,i} \leq 0$  for all i then  $\|\widehat{p}_t\|_1 = 0$  and therefore both  $\|\widehat{p}_t\|_1 \sum_{i=1}^d p_{t,i}(g_{t,i} - \langle \boldsymbol{g}_t, \boldsymbol{p}_t \rangle)$  and  $\sum_{i:x_{t,i}>0} \max(x_{t,i},0)(g_{t,i} - \langle \boldsymbol{g}_t, \boldsymbol{p}_t \rangle)$  are trivially zero. If  $\|\widehat{p}_t\|_1 > 0$  then  $\max(x_{t,i},0) = \widehat{p}_{t,i} = \|\widehat{p}_t\|_1 p_{t,i}$  for all i.

From the assumption on  $\mathcal{A}$ , for the arm i, we have for any sequence  $\{c_t'\}_{t=1}^T$  such that  $c_t' \in [-1,1]$  that

Wealth<sub>T,i</sub> = 
$$\pi_i + \sum_{t=1}^{T} c_t' x_t \ge \pi_i \exp\left(f_T\left(\sum_{t=1}^{T} c_t'\right)\right)$$
. (10.5)

So, inequality  $\langle \boldsymbol{c}_t, \boldsymbol{x}_t \rangle \leq 0$  and (10.5) imply

$$\sum_{i=1}^{d} \pi_i \exp\left(f_T\left(\sum_{t=1}^{T} c_{t,i}\right)\right) \le 1 + \sum_{i=1}^{d} \sum_{t=1}^{T} c_{t,i} x_{t,i} \le 1.$$
(10.6)

#### Algorithm 10.4 Learning with Expert Advice based on KT Bettors

**Require:** Number of experts d, prior distribution  $\pi \in \Delta^{d-1}$ , number of rounds T

1: **for** 
$$t=1,2,\ldots,T$$
 **do**  
2: Set  $x_{t,i}=\frac{\sum_{j=1}^{t-1}c_{j,i}}{t}\left(\pi_i+\sum_{j=1}^{t-1}c_{j,i}x_{j,i}\right)$  for  $i=1,\ldots,d$ 

3: Set 
$$\widehat{p}_{t,i} = \max(x_{t,i}, 0)$$
 for  $i = 1, \ldots, d$ 

4: Predict with 
$$\boldsymbol{p}_t = \begin{cases} \widehat{\boldsymbol{p}}_t / \|\widehat{\boldsymbol{p}}_t\|_1 & \text{if } \|\widehat{\boldsymbol{p}}_t\|_1 > 0 \\ \pi & \text{if } \|\widehat{\boldsymbol{p}}_t\|_1 = 0 \end{cases}$$

5: Receive loss vector 
$$\mathbf{g}_t \in [0,1]^d$$
6: Set  $c_{t,i} = \begin{cases} \langle \mathbf{g}_t, \mathbf{p}_t \rangle - g_{t,i}, & \text{if } x_{t,i} > 0 \\ \max(\langle \mathbf{g}_t, \mathbf{p}_t \rangle - g_{t,i}, 0), & \text{if } x_{t,i} \leq 0 \end{cases}$  for  $i = 1, \dots, d$ 

Now, for any competitor  $u \in \Delta^{d-1}$ ,

$$\begin{aligned} \operatorname{Regret}_{T}(\boldsymbol{u}) &= \sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{p}_{t} - \boldsymbol{u} \rangle \\ &= \sum_{t=1}^{T} \sum_{i=1}^{d} u_{i} \left( \langle \boldsymbol{g}_{t}, \boldsymbol{p}_{t} \rangle - g_{t,i} \right) \\ &\leq \sum_{t=1}^{T} \sum_{i=1}^{d} u_{i} c_{t,i} \qquad \text{(by definition of } c_{t,i} \text{)} \\ &\leq \sum_{i=1}^{d} u_{i} h \left( f_{T} \left( \sum_{t=1}^{T} c_{t,i} \right) \right) \qquad \text{(definition of the } h(x) \text{)} \\ &\leq h \left[ \sum_{i=1}^{d} u_{i} f_{T} \left( \sum_{t=1}^{T} c_{t,i} \right) \right] \qquad \text{(by concavity of } h \text{ and Jensen inequality)} \\ &\leq h \left[ \operatorname{KL}(\boldsymbol{u}; \boldsymbol{\pi}) + \ln \left( \sum_{i=1}^{d} \pi_{i} \exp \left( f_{T} \left( \sum_{t=1}^{T} c_{t,i} \right) \right) \right) \right] \qquad \text{(Fenchel-Young inequality)} \\ &\leq h \left( \operatorname{KL}(\boldsymbol{u}; \boldsymbol{\pi}) \right) \qquad \text{(by (10.6))} \, . \end{aligned}$$

Now, we could think to use the KT bettor with this theorem, obtaining the Algorithm 10.4. Unfortunately, this algorithm obtains a sub-optimal regret guarantee. In fact, remembering the lower bound on the wealth of KT and setting  $h(x) = \sqrt{4T(x + \frac{1}{2} \ln T + K)}$  where K is a universal constant, we have

$$\operatorname{Regret}_{T}(\boldsymbol{u}) = \mathcal{O}(\sqrt{T(\operatorname{KL}(\boldsymbol{u};\boldsymbol{\pi}) + \ln T)})$$
.

We might think that the  $\ln T$  is the price we have to pay to adapt to the unknown competitor u. However, it turns out it can be removed. In the next section, we see how to change the KT strategy to obtain the optimal guarantee.

#### A Betting Strategy that Loses at Most a Constant Fraction of Money 10.6.1

In the reduction before, if we use the KT betting strategy we would have a  $\ln T$  term under the square root. It turns out that we can avoid that term if we know the number of rounds beforehand. Then, in case T is unknown we can just use a doubling trick, paying only a constant multiplicative factor in the regret.

The logarithmic term in the regret comes from the fact that the lower bound on the wealth is

$$\mathcal{O}\left(\frac{1}{\sqrt{T}}\exp\left(\frac{\left(\sum_{t=1}^{T}c_{t}\right)^{2}}{4T}\right)\right)$$
.

Note that in the case in which the number of heads in the sequence is equal to the number of heads, so that  $\sum_{t=1}^{T} c_t = 0$ , the guaranteed wealth becomes proportional to  $\frac{1}{\sqrt{T}}$ . So, for T that goes to infinity the bettor will lose all of its money.

Instead, we need a more conservative strategy that guarantees

$$\mathcal{O}\left(\alpha \exp\left(\frac{\left(\sum_{t=1}^{T} c_{t}\right)^{2}}{4T}\right)\right),$$

for  $\alpha$  small enough and independent of T. In this case, the betting strategy has to pace its betting, possibly with the knowledge of the duration of the game, so that even in the case that the number of heads is equal to the number of tails it will only lose a fraction of its money. At the same time, it will still gain an exponential amount of money when the coin outcomes are biased towards one side.

We will prove that this is possible, designing a new betting strategy.

Denote by  $S_t = \sum_{i=1}^t c_i$  for t = 1, ..., T and define

$$F_t(x) = \epsilon \exp\left(\frac{x^2}{2(t+T)} - \sum_{i=1}^t \frac{1}{2(i+T)}\right),$$
 (10.7)

$$\beta_t = \frac{F_t(S_{t-1}+1) - F_t(S_{t-1}-1)}{F_t(S_{t-1}+1) + F_t(S_{t-1}-1)}.$$
(10.8)

Note that if

$$(1 + \beta_t c_t) F_{t-1} \left( \sum_{i=1}^{t-1} c_i \right) \ge F_t \left( \sum_{i=1}^t c_i \right), \tag{10.9}$$

then, by induction,  $\operatorname{Wealth}_T \geq F_T\left(\sum_{t=1}^T c_t\right)$ . In fact, we have

Wealth<sub>t</sub> = 
$$(1 + \beta_t c_t)$$
 Wealth<sub>t-1</sub>  $\geq (1 + \beta_t c_t) F_{t-1} \left( \sum_{i=1}^{t-1} c_i \right) \geq F_t \left( \sum_{i=1}^t c_i \right)$ .

Hence, we have to prove that (10.9) is true in order to guarantee a minimum wealth of our betting strategy.

First, given that  $\ln(1+\beta_t c) - \frac{(x+c)^2}{2(t+T)}$  is a concave function of c, we have

$$\min_{c \in [-1,1]} \ln(1+\beta_t c) - \frac{(x+c)^2}{2(t+T)} = \min\left(\ln(1+\beta_t) - \frac{(x+1)^2}{2(t+T)}, \ln(1-\beta_t) - \frac{(x-1)^2}{2(t+T)}\right).$$

Also, our choice of  $\beta_t$  makes the two quantities above equal with  $x = S_{t-1}$ , that is

$$\ln(1+\beta_t) - \ln F_t(S_{t-1}+1) = \ln(1-\beta_t) - \ln F_t(S_{t-1}-1)$$

For other choices of  $\beta_t$ , the two alternatives would be different and the minimum one could always be the one picked by the adversary. Instead, making the two choices worst outcomes equivalent, we minimize the damage of the adversarial

choice of the outcomes of the coin. So, we have that

$$\begin{split} \ln(1+\beta_t c_t) - \ln F_t(S_t) &= \ln(1+\beta_t c_t) + F_t(S_{t-1} + c_t) \\ &\geq \min_{c \in [-1,1]} \ln(1+\beta_t c) + \ln F_t(S_{t-1} + c) \\ &= - \ln \frac{F_t(S_{t-1} + 1) + F_t(S_{t-1} - 1)}{2} \\ &= - \ln \left[ \exp\left(\frac{S_{t-1}^2 + 1}{2(t+T)} - \sum_{i=1}^t \frac{1}{2(i+T)}\right) \frac{1}{2} \left( \exp\left(\frac{S_{t-1}}{t+T}\right) + \exp\left(\frac{-S_{t-1}}{t+T}\right) \right) \right] \\ &= - \frac{S_{t-1}^2 + 1}{2(t+T)} - \ln \cosh \frac{S_{t-1}}{t+T} + \sum_{i=1}^t \frac{1}{2(i+T)} \\ &\geq - \frac{S_{t-1}^2}{2(t+T)} - \frac{S_{t-1}^2}{2(t+T)^2} + \sum_{i=1}^{t-1} \frac{1}{2(i+T)} \\ &\geq - \frac{S_{t-1}^2}{2(t+T)} - \frac{S_{t-1}^2}{2(t+T)(t-1+T)} + \sum_{i=1}^{t-1} \frac{1}{2(i+T)} \\ &= - \frac{S_{t-1}^2}{2(t-1+T)} + \sum_{i=1}^{t-1} \frac{1}{2(i+T)} \\ &= - \ln F_{t-1}(S_{t-1}), \end{split}$$

where in the second equality we used the definition of  $\beta_t$  and in the second inequality we used the fact that  $\ln \cosh(x) \le \frac{x^2}{2}, \forall x$ .

Hence, given that (10.9) is true, this strategy guarantees

$$\operatorname{Wealth}_{T} \geq \exp\left(\frac{\left(\sum_{t=1}^{T} c_{t}\right)^{2}}{4T} - \sum_{t=1}^{T} \frac{1}{2(i+T)}\right) \geq \exp\left(\frac{\left(\sum_{t=1}^{T} c_{t}\right)^{2}}{4T} - \frac{1}{2}\ln 2\right) = \frac{\sqrt{2}}{2}\exp\left(\frac{\left(\sum_{t=1}^{T} c_{t}\right)^{2}}{4T}\right).$$

We can now use this betting strategy in the expert reduction in Theorem 10.13, setting  $h(x) = \sqrt{4T(x + \frac{1}{2}\ln 2)}$ , to have

$$\operatorname{Regret}_{T}(\boldsymbol{u}) \leq \sqrt{4T\left(\operatorname{KL}(\boldsymbol{u};\boldsymbol{\pi}) + \frac{1}{2}\ln 2\right)}$$
 (10.10)

Note that this betting strategy could also be used in the OCO reduction. Given that we removed the logarithmic term in the exponent, in the 1-dimensional case, we would obtain a regret of

$$\operatorname{Regret}_T(u) \leq \mathcal{O}\left(|u|\sqrt{T\ln\left(\frac{|u|\sqrt{T}}{\epsilon}+1\right)+\epsilon}\right),$$

where we gained in the  $\sqrt{T}$  term inside the logarithmic, instead of the T term of the KT algorithm. This implies that now we can set  $\epsilon$  to  $\sqrt{T}$  and obtain an asymptotic rate of  $\mathcal{O}(\sqrt{T})$  rather than  $\mathcal{O}(\sqrt{T \ln T})$ .

### 10.7 Reduction to Sleeping Experts

Consider the learning with sleeping experts setting from Section 9.2. We will show how to easily design a parameter-free algorithm for this setting.

Consider to use a KT to solve the online linear optimization in  $\mathbb{R}$ . We slightly modify KT to ignore the rounds where the gradients are zero:

$$x_t = \frac{-\sum_{j=1}^{t-1} g_j}{1 + \sum_{j=1}^{t-1} \mathbf{1}[g_j \neq 0]} \left( \epsilon - \sum_{j=1}^{t-1} g_j x_j \right) .$$

It is easy to show—see Exercise 10.3—that this algorithm will guarantee the following regret upper bound:

$$\sum_{t=1}^{T} g_t(x_t - u) = \mathcal{O}\left(|u|\sqrt{\sum_{t=1}^{T} \mathbf{1}[g_t \neq 0] \ln \frac{\sum_{t=1}^{T} \mathbf{1}[g_t \neq 0]}{\epsilon}} + \epsilon\right), \ \forall u \in \mathbb{R}.$$

Using a black-box reduction to constrain it to  $\mathbb{R}_{\geq 0}$ , as in Example 9.9, we have

$$\tilde{g}_{t} = \begin{cases} \min(g_{t}, 0), & z_{t} < 0 \\ g_{t}, & z_{t} \ge 0 \end{cases} 
z_{t} = \frac{-\sum_{j=1}^{t-1} \tilde{g}_{j}}{1 + \sum_{j=1}^{t-1} \mathbf{1}[\tilde{g}_{j} \ne 0]} \left( \epsilon - \sum_{j=1}^{t-1} \tilde{g}_{j} z_{j} \right) 
x_{t} = \max(z_{t}, 0).$$

and obtain a regret of  $\mathcal{O}(u\sqrt{T'\ln(T'/\epsilon+1)}+\epsilon)$  where T' is the number of times that  $\tilde{g}_t\neq 0$ . Next, we use this algorithm to produce predictions over  $\mathbb{R}^d_{\geq 0}$ , using each 1d algorithm on each coordinate. We set the  $\epsilon_i$  such that  $\sum_{i=1}^d \epsilon_i = 1$ . So, we obtain a regret of  $\mathcal{O}(1+\sum_{i=1}^d u_i\sqrt{T'_i\ln(T'_i/\epsilon_i+1)})$ . Finally, use a sleeping expert reduction from  $\mathbb{R}^d_{>0}$ :

$$\hat{g}_{t,i} = a_{t,i}(g_{t,i} - \langle \mathbf{g}_t, \mathbf{x}_t \rangle), i = 1, \dots, d$$

$$\tilde{g}_{t,i} = \begin{cases} \min(\hat{g}_{t,i}, 0), & z_{t,i} < 0 \\ \hat{g}_{t,i}, & z_{t,i} \ge 0 \end{cases}, i = 1, \dots, d$$

$$z_{t,i} = \frac{-\sum_{j=1}^{t-1} \tilde{g}_{j,i}}{1 + \sum_{j=1}^{t-1} \mathbf{1}[\tilde{g}_{j,i} \ne 0]} \left( \epsilon_i - \sum_{j=1}^{t-1} \tilde{g}_{j,i} z_{j,i} \right), i = 1, \dots, d$$

$$x_{t,i} = \frac{a_{t,i} \max(z_{t,i}, 0)}{\sum_{j=1}^{d} a_{t,j} \max(z_{t,i}, 0)}, i = 1, \dots, d.$$

Moreover, given that  $a_{t,i} = 0$  implies  $\tilde{g}_{t,i} = 0$ , the upper bound on the sleeping expert regret of the final algorithm against any expert i is  $\mathcal{O}(\sqrt{\sum_{t=1}^{T} a_{t,i} \ln \frac{\sum_{t=1}^{T} a_{t,i}}{\epsilon_i}} + 1)$ , that depends on the number of rounds that the expert i was active.

### 10.8 History Bits

The keyword "parameter-free" has been introduced in Chaudhuri et al. [2009] for a similar strategy for the learning with expert problem. It is now used as an umbrella term for all online algorithms that *guarantee the optimal regret uniformly over the competitor class*. Another less used name to denote the exact same property is "comparator-adaptive" [van der Hoeven et al., 2020]. Note that, given the allure of the name "parameter-free", the term has been adopted in many other domains, with many different meanings. However, when used in the online learning literature, it has *only* the meaning we specify above. This means that in this literature "parameter-free" algorithms might still require the knowledge of other characteristics of the problem, for example, the Lipschitz constant of the losses or the number of rounds. This is fine: it is a technical term and we can assign to it any definition we like, as for "smooth" or "universal".

The first algorithm for 1-d parameter-free OCO is from Streeter and McMahan [2012], but the bound was suboptimal. The algorithm was then extended to Hilbert spaces in Orabona [2013], still with a suboptimal bound. The optimal bound in Hilbert space was obtained in McMahan and Orabona [2014] that also obtains the regret upper bound

$$\mathcal{O}\left(\|\boldsymbol{u}\|_2\sqrt{T\ln\left(rac{\sqrt{T}\|\boldsymbol{u}\|_2}{\epsilon}+1
ight)}+\epsilon
ight),$$

where  $\epsilon$  is a parameter of the algorithm. This variant allows to remove the factor T in the logarithm by setting  $\epsilon = \mathcal{O}(\sqrt{T})$ , at the price of having a  $\mathcal{O}(\sqrt{T})$  regret versus u = 0. The optimal constant for this kind of guarantees is obtained in Zhang et al. [2022] through a PDE-based analysis, proving also a matching lower bound.

The idea of using a coin-betting to do parameter-free OCO was introduced in Orabona and Pál [2016]. A different reduction from a betting algorithm to the specific case of linear regression with square loss was proposed by Vovk [2006]. The Krichevsky-Trofimov algorithm is from Krichevsky and Trofimov [1981] and its extension to the "continuous coin" is from Orabona and Pál [2016]. The regret/reward duality relationship was proved for the first time in McMahan and Orabona [2014]. Lemma C.3 is from Orabona and Pál [2016]. There are also more refined betting algorithms that allow to obtain parameter-free OCO algorithms that depend on the sum of the squared norm of the subgradients, rather than time [Cutkosky and Orabona, 2018], also in a scale-free way [Mhammedi and Koolen, 2020]. Recently, parameter-free algorithms have been also extended to some non-convex functions in the stochastic setting [Orabona and Pál, 2021].

The approach of using a coordinate-wise version of the coin-betting algorithm was proposed in the first paper on parameter-free OLO in Streeter and McMahan [2012]. Recently, the same approach with a special coin-betting algorithm was also used for optimization of deep neural networks [Orabona and Tommasi, 2017]. The idea of combining two parameter-free OLO algorithms to obtain the best of the two guarantees is from Cutkosky [2019b].

Orabona and Pál [2016] proposed a different way to transform a coin-betting algorithm into an OCO algorithm that works in  $\mathbb{R}^d$  or even in Hilbert spaces. However, that approach seems to work on for the  $L_2$  norm and it is not a black-box reduction. That said, the reduction in Orabona and Pál [2016] seems to have a better empirical performance compared to the one in Theorem 9.16.

There are also reductions that allow to transform an unconstrained OCO learner into a constrained one [Cutkosky and Orabona, 2018]. They work constructing a Lipschitz barrier function on the domain and passing to the algorithm the original subgradients plus the subgradients of the barrier function.

The first parameter-free algorithm for experts is from Chaudhuri et al. [2009], named NormalHedge, where they introduced the concept of  $\epsilon$ -quantile regret and obtained a bound of  $\mathcal{O}(\sqrt{(T+\ln^2 d)(1+\ln\frac{1}{\epsilon})})$  as  $T\to\infty$ , but without a closed formula update. Then, Chernov and Vovk [2010] removed the spurious dependency on d, again with an update without a closed form. Orabona and Pál [2016] showed that this guarantee can be efficiently obtained through the novel reduction to coin-betting in Theorem 10.13. Later, this kind of regret guarantees were improved to depend on the sum of the squared losses rather than on time, but with an additional  $\ln \ln T$  factor, in the Squint algorithm [Koolen and van Erven, 2015]. It is worth noting that the Squint algorithm can be interpreted exactly as a coin-betting algorithm plus the reduction in Theorem 10.13. The first lower bound for the  $\epsilon$ -quantile regret is proved in Negrea et al. [2021].

The betting strategy in (10.7) and (10.8) are new, and derived from the shifted-KT potentials in Orabona and Pál [2016]. The guarantee is the same obtained by the shifted-KT potentials, but the analysis can be done without knowing the properties of the Gamma function.

The variant of KT in Section 10.7 that updates only when  $g_t \neq 0$  appeared for the first time in Chen et al. [2022]. Recently, coin-betting algorithms have found numerous applications, as the design of parameter-free online multitask learning algorithms [Denevi et al., 2020], parameter-free particle-based algorithms [Sharrock and Nemeth, 2023, Sharrock et al., 2023a,b], and the derivation of time-uniform concentration inequalities (see Chapter 13).

#### 10.9 Exercises

**Problem 10.1.** Prove that  $\ell_t(x) = -\ln(1 + z_t x)$  with  $\mathcal{V} = \{x \in \mathbb{R} : |x| \le 1/2\}$  and  $|z_t| \le 1$ , t = 1, ..., T are exp-concave. Then, using the Online Newton Step Algorithm, give an algorithm and a regret bound for a game with

these losses. Finally, show a wealth guarantee of the corresponding coin-betting strategy.

**Problem 10.2.** Using the same proof technique in the section, find a betting strategy whose wealth depends on  $\sum_{t=1}^{T} |c_t|$  rather than on T.

**Problem 10.3.** Consider the variant of KT for OLO that predicts with  $x_t = \frac{-\sum_{t=1}^{t-1} g_j}{1+\sum_{j=1}^{t-1} \mathbf{1}[g_j \neq 0]} \left(\epsilon - \sum_{j=1}^{t-1} g_j x_j\right)$ . Prove that it guarantees a regret of  $\mathcal{O}(|u|\sqrt{\sum_{t=1}^{T} \mathbf{1}[g_t \neq 0]} \ln \frac{\sum_{t=1}^{T} \mathbf{1}[g_t \neq 0]}{\epsilon} + \epsilon)$  for any  $u \in \mathbb{R}$  and the linear losses  $\ell_t(x) = g_t x$ .

## **Chapter 11**

# **Multi-Armed Bandit**

The Multi-Armed Bandit setting is similar to the Learning with Expert Advice (LEA) setting: In each round, we select one expert  $A_t$ , but, differently from the full-information setting, we only observe the loss  $g_{t,A_t}$  of that expert. The aim is still to compete with the cumulative loss of the best expert in hindsight. The observed losses can be adversarial or stochastic, giving rise to adversarial and stochastic multi-armed bandits.

#### 11.1 Adversarial Multi-Armed Bandit

As in the learning with expert case, we need randomization in order to have a sublinear regret. Indeed, this is just a harder problem than LEA. However, we will assume that the adversary is **oblivious**, that is, he decides the losses of all the rounds before the game starts, but with the knowledge of the online algorithm. This makes the losses deterministic quantities and it avoids the inadequacy in our definition of regret when the adversary is adaptive to the past algorithm's plays (see Arora et al. [2012]).

This kind of problems where we do not receive the full-information, i.e., we do not observe the loss vector, are called **bandit problems**. The name comes from the problem of a gambler who plays a pool of slot machines, that can be called "one-armed bandits". On each round, the gambler places his bet on a slot machine and his goal is to win almost as much money as if he had known in advance which slot machine would return the maximal total reward.

In this problem, we clearly have an *exploration-exploitation trade-off*. In fact, on one hand we would like to play at the slot machine which, based on previous rounds, we believe will give us the biggest win. On the other hand, we have to explore the slot machines to find the best ones. On each round, we have to solve this trade-off.

Given that we do not observe completely the loss, we cannot use our two frameworks: Online Mirror Descent (OMD) and Follow-The-Regularized-Leader (FTRL) both needs the loss functions or at least lower bounds to them.

One way to solve this issue is to construct stochastic estimates of the unknown losses. This is a natural choice given that the prediction strategy has to be a randomized one even in the full-information setting, as we saw in Section 6.8. So, in each round t we construct a probability distribution over the arms  $x_t$  and we sample one action  $A_t$  according to this probability distribution. Then, we only observe the coordinate  $A_t$  of the loss vector  $\mathbf{g}_t \in \mathbb{R}^d$ . One possibility to have a stochastic estimate of the losses is to use an importance-weighted estimator: Construct the estimator  $\tilde{\mathbf{g}}_t$  of the unknown vector  $\mathbf{g}_t$  in the following way:

$$\tilde{g}_{t,i} = \begin{cases} rac{g_{t,i}}{x_{t,i}}, & i = A_t \\ 0, & ext{otherwise} \end{cases}$$
 for  $i = 1, \dots, d$ .

Note that this estimator has all the coordinates equal to 0, except for the coordinate corresponding to the arm that was pulled.

This estimator is unbiased, that is  $\mathbb{E}_{A_t}[\tilde{g}_t] = g_t$ . To see why, note that we can rewrite  $\tilde{g}_{t,i}$  as  $\mathbf{1}[A_t = i] \frac{g_{t,i}}{x_{t,i}}$  for  $i = 1, \ldots, d$  and  $\mathbb{E}_{A_t}[\mathbf{1}[A_t = i]] = x_{t,i}$ . Hence, for  $i = 1, \ldots, d$ , we have

$$\mathbb{E}_{A_t}[\tilde{g}_{t,i}] = \mathbb{E}_{A_t} \left[ \mathbf{1}[A_t = i] \frac{g_{t,i}}{x_{t,i}} \right] = \frac{g_{t,i}}{x_{t,i}} \mathbb{E}_{A_t}[\mathbf{1}[A_t = i]] = g_{t,i} .$$

Let's also calculate the (uncentered) variance of the coordinates of this estimator. We have

$$\mathbb{E}_{A_t}[\tilde{g}_{t,i}^2] = \mathbb{E}_{A_t} \left[ \mathbf{1}[A_t = i] \frac{g_{t,i}^2}{x_{t,i}^2} \right] = \frac{g_{t,i}^2}{x_{t,i}} \; .$$

We can now think of using OMD with these estimated losses and an entropic regularizer. Of course, a similar reasoning can also be done with FTRL. Hence, assume  $\|g_t\|_{\infty} \leq L_{\infty}$  and set  $\psi : \mathbb{R}^d_{\geq 0} \to \mathbb{R}$  defined as  $\psi(x) = \sum_{i=1}^d x_i \ln x_i$ , that is the unnormalized negative entropy. Also, set  $x_1 = [1/d, \dots, 1/d]$ . Using the OMD analysis, we have

$$\sum_{t=1}^T \langle \tilde{\boldsymbol{g}}_t, \boldsymbol{x}_t \rangle - \sum_{t=1}^T \langle \tilde{\boldsymbol{g}}_t, \boldsymbol{u} \rangle \leq \frac{\ln d}{\eta} + \frac{\eta}{2} \sum_{t=1}^T \|\tilde{\boldsymbol{g}}_t\|_{\infty}^2 .$$

We can now take the expectation at both sides and use the fact that

$$\mathbb{E}[\|\tilde{\boldsymbol{g}}_t\|_{\infty}^2] = \mathbb{E}\left[\frac{g_{t,A_t}^2}{x_{t,A_t}^2}\right] = \mathbb{E}\left[\mathbb{E}\left[\frac{g_{t,A_t}^2}{x_{t,A_t}^2}\middle|A_1,\ldots,A_{t-1}\right]\right] = \mathbb{E}\left[\sum_{i=1}^d \frac{g_{t,i}^2}{x_{t,i}}\right],$$

to get

$$\mathbb{E}\left[\sum_{t=1}^{T} g_{t,A_{t}}\right] - \sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{u} \rangle = \mathbb{E}\left[\sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} \rangle\right] - \sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{u} \rangle = \mathbb{E}\left[\sum_{t=1}^{T} \langle \tilde{\boldsymbol{g}}_{t}, \boldsymbol{x}_{t} \rangle - \sum_{t=1}^{T} \langle \tilde{\boldsymbol{g}}_{t}, \boldsymbol{u} \rangle\right] \\
\leq \frac{\ln d}{\eta} + \frac{\eta}{2} \sum_{t=1}^{T} \mathbb{E}[\|\tilde{\boldsymbol{g}}_{t}\|_{\infty}^{2}] \leq \frac{\ln d}{\eta} + \frac{\eta}{2} \sum_{t=1}^{T} \sum_{i=1}^{d} \mathbb{E}\left[\frac{g_{t,i}^{2}}{x_{t,i}}\right], \tag{11.1}$$

where in the last inequality we upper bounded the max over the squared coordinates with their sum to easily calculate the expectation. We are now in troubles, because the terms in the sum scale as  $\max_{i=1,\dots,d} \frac{1}{x_{t,i}}$ . So, we need a way to control the smallest probability over the arms.

One way to do it, is to take a convex combination of  $x_t$  and a uniform probability. That is, we can predict with  $\tilde{x}_t = (1 - \alpha)x_t + \alpha[1/d, \dots, 1/d]^\top$ , where  $\alpha$  will be chosen in the following. So,  $\alpha$  can be seen as the minimum amount of exploration we require to the algorithm. Its value will be chosen by the regret analysis to optimally trade-off exploration vs exploitation. The resulting algorithm is in Algorithm 11.1.

#### Algorithm 11.1 Exponential Weights with Explicit Exploration for Multi-Armed Bandit

**Require:**  $\eta, \alpha > 0$ 

- 1: Set  $x_1 = [1/d, \dots, 1/d]$
- 2: for t = 1 to T do
- 3: Set  $\tilde{\boldsymbol{x}}_t = (1 \alpha)\boldsymbol{x}_t + \alpha[1/d, \dots, 1/d]^{\top}$
- 4: Draw  $A_t$  according to  $P(A_t = i) = \tilde{x}_{t,i}$
- 5: Select expert  $A_t$
- 6: Observe *only* the loss of the selected arm  $g_{t,A_t} \in [-L_\infty, L_\infty]$  and pay it
- 7: Construct the estimate  $\tilde{g}_{t,i} = \begin{cases} \frac{g_{t,i}}{\tilde{x}_{t,i}}, & i = A_t \\ 0, & \text{otherwise} \end{cases}$  for  $i = 1, \dots, d$
- 8:  $x_{t+1,i} \propto x_{t,i} \exp(-\eta \tilde{g}_{t,i}), i = 1, \dots, d$
- 9: end for

The same probability distribution is used in the estimator:

$$\tilde{g}_{t,i} = \begin{cases} \frac{g_{t,i}}{\bar{x}_{t,i}}, & i = A_t \\ 0, & \text{otherwise} \end{cases} \text{ for } i = 1, \dots, d.$$
(11.2)

So, we now have that  $\frac{1}{\tilde{x}_{t,i}} \leq \frac{d}{\alpha}$ . However, we pay a price in the bias introduced:

$$\sum_{t=1}^{T} \langle \tilde{\boldsymbol{g}}_t, \tilde{\boldsymbol{x}}_t - \boldsymbol{u} \rangle = (1 - \alpha) \sum_{t=1}^{T} \langle \tilde{\boldsymbol{g}}_t, \boldsymbol{x}_t - \boldsymbol{u} \rangle + \frac{\alpha}{d} \sum_{t=1}^{T} \sum_{i=1}^{d} \tilde{\boldsymbol{g}}_{t,i} - \alpha \sum_{t=1}^{T} \langle \tilde{\boldsymbol{g}}_t, \boldsymbol{u} \rangle.$$

Observing that  $\mathbb{E}[\sum_{i=1}^d \tilde{g}_{t,i}] = \sum_{i=1}^d g_{t,i} \leq dL_{\infty}$  and  $\mathbb{E}[-\langle \tilde{\boldsymbol{g}}_t, \boldsymbol{u} \rangle] = -\langle \boldsymbol{g}_t, \boldsymbol{u} \rangle \leq L_{\infty}$ , we have

$$\mathbb{E}\left[\sum_{t=1}^{T} \langle \tilde{\boldsymbol{g}}_t, \tilde{\boldsymbol{x}}_t - \boldsymbol{u} \rangle\right] \leq (1 - \alpha) \mathbb{E}\left[\sum_{t=1}^{T} \langle \tilde{\boldsymbol{g}}_t, \boldsymbol{x}_t - \boldsymbol{u} \rangle\right] + 2\alpha L_{\infty} T = (1 - \alpha) \mathbb{E}[\operatorname{Regret}_T(\boldsymbol{u})] + 2\alpha L_{\infty} T.$$

Putting together the last inequality and the upper bound to the expected regret in (11.1), we have

$$\mathbb{E}\left[\sum_{t=1}^{T} g_{t,A_t}\right] - \sum_{t=1}^{T} \langle \boldsymbol{g}_t, \boldsymbol{u} \rangle \leq \frac{(1-\alpha) \ln d}{\eta} + \frac{(1-\alpha) \eta d^2 L_{\infty}^2 T}{2\alpha} + 2\alpha L_{\infty} T \leq \frac{\ln d}{\eta} + \frac{\eta d^2 L_{\infty}^2 T}{2\alpha} + 2\alpha L_{\infty} T.$$

Setting 
$$\alpha \propto \sqrt{d^2 L_\infty \eta}$$
 and  $\eta \propto \left(\frac{\ln d}{dL_\infty^{3/2}T}\right)^{2/3}$ , we obtain a regret of  $\mathcal{O}(L_\infty (dT)^{2/3} \ln^{1/3} d)$  as  $T \to \infty$ .

We did obtain a sublinear regret, but it is way worse than the  $\mathcal{O}(\sqrt{T \ln d})$  of the full-information case. However, while it is expected that the bandit case must be more difficult than the full information one, it turns out that this is not the optimal strategy.

#### 11.1.1 Exponential-weight algorithm for Exploration and Exploitation: Exp3

It turns out that the algorithm above actually works, even without mixing the output of the algorithm with the uniform distribution! We were just too loose in our regret guarantee. So, we will analyse the following algorithm, that is called Exponential-weight algorithm for Exploration and Exploitation (Exp3), that is nothing else than OMD with entropic regularizer and stochastic estimates of the losses.

#### Algorithm 11.2 Exp3

**Require:**  $\eta > 0$ 

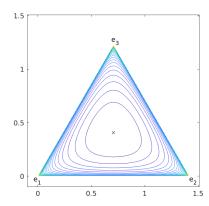

- 1:  $\boldsymbol{x}_1 = [1/d, \dots, 1/d]$
- 2: for t = 1 to T do
- 3: Draw  $A_t$  according to  $P(A_t = i) = x_{t,i}$
- 4: Select expert  $A_t$
- 5: Observe *only* the loss of the selected arm  $g_{t,A_t}$  and pay it
- 6: Construct the estimate  $\tilde{g}_{t,i} = \begin{cases} \frac{g_{t,i}}{x_{t,i}}, & i = A_t \\ 0, & \text{otherwise} \end{cases}$  for  $i = 1, \dots, d$
- 7:  $x_{t+1,i} \propto x_{t,i} \exp(-\eta \tilde{g}_{t,i}), i = 1, ..., d$
- 8: end for

This time we will use the local norm regret bound for OMD. The reason is that, when we use the strong convexity, we are upper bounding the terms in the sum with the inverse of the smallest eigenvalue of the Hessian of the regularizer. However, we can do better if we consider the local norms. In fact, in the coordinates where  $x_t$  is small, we have a smaller growth of the divergence. This can be seen also graphically in Figure 11.1. Indeed, for the entropic regularizer, we have that the Hessian is a diagonal matrix:

$$(\nabla^2 \psi(\boldsymbol{x}))_{ii} = \frac{1}{x_i}, \ i = 1, \dots, d.$$

Summing the inequality of Lemma 6.33 with  $t = 1, \dots, T$ , the above expression of the Hessian gives a regret of

$$\sum_{t=1}^{T} \langle \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{u} \rangle \leq \frac{B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_1)}{\eta} + \frac{\eta}{2} \sum_{t=1}^{T} \sum_{i=1}^{d} z_{t,i} g_{t,i}^2,$$

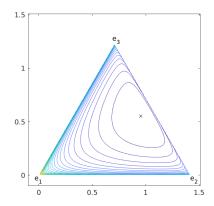

Figure 11.1: Contour plots of the KL divergence in 3-dimensions when  $x_t = [1/3, 1/3, 1/3]$  (left) and when  $x_t = [0.1, 0.45, 0.45]$  (right).

where  $z_t = \alpha_t x_t + (1 - \alpha_t) x_{t+1}$  and  $\alpha_t \in [0, 1]$ . Note that for any  $\alpha_t \in [0, 1]$   $z_t$  is in the probability simplex, so this upper bound is always better than

$$\sum_{t=1}^T \langle \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{u} \rangle \leq \frac{B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_1)}{\eta} + \frac{\eta}{2} \sum_{t=1}^T \|\boldsymbol{g}_t\|_{\infty}^2,$$

that we derived just using the strong convexity of the entropic regularizer.

However, we do not know the exact value of  $z_t$ , but only that it is on the line segment between  $x_t$  and  $x_{t+1}$ . Yet, if you could say that  $z_{t,i} \propto x_{t,i}$ , in the bandit case we would obtain an expected regret guarantee of  $\mathcal{O}(\sqrt{dT \ln d})$ , greatly improving the bound we proved above! In other words, it might be possible to get the regret guarantee

$$\sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} \rangle - \sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{u} \rangle \leq \frac{\ln d}{\eta} + \frac{\eta}{2} \sum_{t=1}^{T} \sum_{i=1}^{d} x_{t,i} g_{t,i}^{2}, \ \forall \boldsymbol{u} \in \mathcal{V},$$
(11.3)

where  $V = \{x \in \mathbb{R}^d : ||x||_1 = 1, x_i \ge 0\}$ . Fortunately, we have an alternative expression in Lemma 6.33 to help us.

**Remark 11.1.** It is possible to prove (11.3) from first principles using the specific properties for the entropic regularizer rather than using Lemma 6.33. However, I prefer not to do it because such proof would not shed any light on what is actually going on.

To use Lemma 6.33, we need a handle on  $z'_{t,i}$  that lies on the line segment between  $\boldsymbol{x}_t$  and  $\tilde{\boldsymbol{x}}_{t+1} = \operatorname{argmin}_{\boldsymbol{x} \in \mathbb{R}^d_{\geq 0}} \langle \boldsymbol{g}_t, \boldsymbol{x} \rangle + \frac{1}{\eta_t} B_{\psi}(\boldsymbol{x}; \boldsymbol{x}_t)$ . Given that we only need an upper bound, we can just take a look at  $x_{t,i}$  and  $\tilde{x}_{t+1,i}$  and see which one is bigger. This is easy to do: using the definition of  $\tilde{\boldsymbol{x}}_t$ , we have

$$\ln(\tilde{x}_{t+1}) + 1 = \ln(x_t) + 1 - \eta q_t$$

that is

$$\tilde{x}_{t+1,i} = x_{t,i} \exp(-\eta g_{t,i}) .$$

Assuming  $|g_{t,i}| \leq L_{\infty}$ , we have  $\tilde{x}_{t+1,i} \leq \exp(\eta L_{\infty}) x_{t,i}$  that implies  $z_{t,i} \leq x_{t,i} \max(1, \exp(\eta L_{\infty}))$ .

Overall, we have the following improved regret guarantee for the Learning with Experts setting with positive losses.

**Theorem 11.2.** Assume  $\|\mathbf{g}_t\|_{\infty} \leq L_{\infty}$  for  $t=1,\ldots,T$ . Let  $\mathcal{V}=\{\mathbf{x}\in\mathbb{R}^d: \|\mathbf{x}\|_1=1, x_i\geq 0\}$  and  $\eta>0$ . Using OMD with the entropic regularizer  $\psi:\mathbb{R}^d_{\geq 0}\to\mathbb{R}$  defined as  $\psi(\mathbf{x})=\sum_{i=1}^d x_i\ln x_i$ , learning rate  $\eta$ , and  $\mathbf{x}_1=[1/d,\ldots,1/d]$  gives the regret guarantee

$$\sum_{t=1}^T \langle \boldsymbol{g}_t, \boldsymbol{x}_t \rangle - \sum_{t=1}^T \langle \boldsymbol{g}_t, \boldsymbol{u} \rangle \leq \frac{\ln d}{\eta} + \frac{\eta \max(1, \exp(\eta L_{\infty}))}{2} \sum_{t=1}^T \sum_{i=1}^d x_{t,i} g_{t,i}^2, \ \forall \boldsymbol{u} \in \mathcal{V} \ .$$

Armed with this new tool, we can now turn our attention again to the multi-armed bandit problem.

Let's now consider the OMD with entropic regularizer, learning rate  $\eta$ , and set  $\tilde{g}_t$  equal to the stochastic estimate of  $g_t$ , as in Algorithm 11.2. Applying Theorem 11.2 and taking the expectation, we have

$$\mathbb{E}\left[\sum_{t=1}^{T} g_{t,A_t}\right] - \sum_{t=1}^{T} \langle \boldsymbol{g}_t, \boldsymbol{u} \rangle = \mathbb{E}\left[\sum_{t=1}^{T} \langle \tilde{\boldsymbol{g}}_t, \boldsymbol{x}_t \rangle - \sum_{t=1}^{T} \langle \tilde{\boldsymbol{g}}_t, \boldsymbol{u} \rangle\right] \leq \frac{\ln d}{\eta} + \frac{\eta}{2} \mathbb{E}\left[\sum_{t=1}^{T} \sum_{i=1}^{d} x_{t,i} \tilde{g}_{t,i}^2\right].$$

Now, focusing on the terms  $\mathbb{E}[x_{t,i}\tilde{g}_{t,i}^2]$ , we have

$$\mathbb{E}\left[\sum_{i=1}^{d} x_{t,i} \tilde{g}_{t,i}^{2}\right] = \mathbb{E}\left[\mathbb{E}\left[\sum_{i=1}^{d} x_{t,i} \tilde{g}_{t,i}^{2} \middle| A_{1}, \dots, A_{t-1}\right]\right] = \mathbb{E}\left[\sum_{i=1}^{d} x_{t,i} \frac{g_{t,i}^{2}}{x_{t,i}}\right] \le dL_{\infty}^{2}.$$
(11.4)

So, setting  $\eta = \sqrt{\frac{2 \ln d}{dL_{co}^2 T}}$ , we have

$$\mathbb{E}\left[\sum_{t=1}^{T} g_{t,A_t}\right] - \sum_{t=1}^{T} \langle \boldsymbol{g}_t, \boldsymbol{u} \rangle \leq L_{\infty} \sqrt{2dT \ln d}.$$

So, with a tighter analysis we showed that, even without an explicit exploration term, OMD with entropic regularizer solves the multi-armed bandit problem paying only a factor  $\sqrt{d}$  more than the full information case. However, this is still not the optimal regret!

In the next section, we will see that changing the regularizer, with the same analysis, will remove the  $\sqrt{\ln d}$  term in the regret.

#### 11.1.2 **Optimal Regret Using OMD with Tsallis Entropy**

In this section, we present the Implicitly Normalized Forecaster (INF) also known as OMD with Tsallis entropy for multi-armed bandit.

Define  $\psi_q: \mathbb{R}^d_{\geq 0} \to \mathbb{R}$  as  $\psi_q(\boldsymbol{x}) = \frac{1}{1-q} \left(1 - \sum_{i=1}^d x_i^q\right)$ , where  $q \in [0,1]$  and in q=1 we extend the function by continuity. This is the negative **Tsallis entropy** of the vector x. This is a strict generalization of the Shannon entropy, because when q goes to 1,  $\psi_q(x)$  converges to the negative (Shannon) entropy of x.

We will instantiate OMD with this regularizer for the multi-armed problem, as in Algorithm 11.3.

# Algorithm 11.3 INF Algorithm (OMD with Tsallis Entropy for Multi-Armed Bandit)

**Require:**  $\eta > 0, q \in [0, 1]$ 

- 1:  $\mathbf{x}_1 = [1/d, \dots, 1/d]$
- 2: for t = 1 to T do
- Draw  $A_t$  according to  $P(A_t = i) = x_{t,i}$
- Select expert  $A_t$
- Observe  $\mathit{only}$  the loss of the selected arm  $g_{t,A_t}$  and pay it
- Construct the estimate  $\tilde{g}_{t,i} = \begin{cases} \frac{g_{t,i}}{x_{t,i}}, & i = A_t \\ 0, & \text{otherwise} \end{cases}$  for  $i = 1, \dots, d$
- $x_{t+1} = \operatorname{argmin}_{x \in \Delta^{d-1}} \eta \langle \tilde{g}_t, x \rangle \frac{1}{1-q} \sum_{i=1}^d x_i^q + \frac{q}{1-q} \sum_{i=1}^d x_{t,i}^{q-1} x_i$
- 8: end for

Note that  $\operatorname{argmin}_{\boldsymbol{x}\in\Delta^{d-1}} \ \psi_q(\boldsymbol{x}) = [\frac{1}{d},\dots,\frac{1}{d}]$  and  $\min_{\boldsymbol{x}} \psi_q(\boldsymbol{x}) = \frac{1-d^{1-q}}{1-q}$ . We will not use any interpretation of this regularizer from the information theory point of view. As we will see in the following, the only reason to choose it is its Hessian. In fact, the Hessian of this regularizer is still diagonal and it is equal to

$$(\nabla^2 \psi_q(\boldsymbol{x}))_{ii} = \frac{q}{x_i^{2-q}} .$$

Now, we can use again the second part of Lemma 6.33. So, for any  $u \in \mathcal{V}$ , we obtain

$$\sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{u} \rangle \leq \frac{B_{\psi_{q}}(\boldsymbol{u}; \boldsymbol{x}_{1})}{\eta} + \frac{\eta}{2} \sum_{t=1}^{T} \boldsymbol{g}_{t}^{\top} (\nabla^{2} \psi_{q}(\boldsymbol{z}_{t}'))^{-1} \boldsymbol{g}_{t} = \frac{d^{1-q} - \sum_{i=1}^{d} u_{i}^{q}}{\eta(1-q)} + \frac{\eta}{2q} \sum_{t=1}^{T} \sum_{i=1}^{d} g_{t,i}^{2} (z_{t,i}')^{2-q},$$

where  $\boldsymbol{z}_t' = \alpha_t \boldsymbol{x}_t + (1 - \alpha_t) \tilde{\boldsymbol{x}}_{t+1}$ ,  $\alpha_t \in [0, 1]$ , and  $\tilde{\boldsymbol{x}}_{t+1} = \operatorname{argmin}_{\boldsymbol{x} \in \mathbb{R}^d_+} \langle \boldsymbol{g}_t, \boldsymbol{x} \rangle + \frac{1}{\eta_t} B_{\psi_q}(\boldsymbol{x}; \boldsymbol{x}_t)$ . As we did for Exp3, now we need an upper bounds to the  $z_{t,i}'$ . From the definition of  $\tilde{\boldsymbol{x}}_{t+1}$  and  $\psi$ , we have

$$\tilde{x}_{t+1,i} = -\frac{q}{1-q} \tilde{x}_{t+1,i}^{q-1} = -\frac{q}{1-q} x_{t,i}^{q-1} - \eta g_{t,i},$$

that is

$$\tilde{x}_{t+1,i} = \frac{x_{t,i}}{\left(1 + \frac{1-q}{q} \eta g_{t,i} x_{t,i}^{1-q}\right)^{\frac{1}{1-q}}}.$$

Assuming  $\|g_t\|_{\infty} \leq L_{\infty}$ , we have  $\tilde{x}_{t+1,i} \leq \frac{x_{t,i}}{\left(1 - \frac{1-q}{q}\eta L_{\infty}\right)^{\frac{1}{1-q}}}$ 

Hence, putting all together, we have

$$\sum_{t=1}^{T} \langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{u} \rangle \leq \frac{d^{1-q} - \sum_{i=1}^{d} u_{i}^{q}}{\eta(1-q)} + \frac{\eta}{2q} \frac{1}{\left(1 - \frac{1-q}{q} \eta L_{\infty}\right)^{\frac{2-q}{1-q}}} \sum_{t=1}^{T} \sum_{i=1}^{d} g_{t,i}^{2} x_{t,i}^{2-q}.$$

We can now specialize the above reasoning, considering q = 1/2 in the Tsallis entropy, to obtain the following

**Theorem 11.3.** Assume  $\|\boldsymbol{g}_t\|_{\infty} \leq L_{\infty}$ . Set q=1/2 and  $\boldsymbol{x}_1=[1/d,\ldots,1/d]$ . Then, for any  $0<\eta\leq \frac{1}{2L_{\infty}}$ , Algorithm 11.3 satisfies

$$\mathbb{E}\left[\sum_{t=1}^{T} g_{t,A_t}\right] - \sum_{t=1}^{T} \langle \boldsymbol{g}_t, \boldsymbol{u} \rangle \leq \frac{2\sqrt{d}}{\eta} + 8\eta\sqrt{d}L_{\infty}^2 T.$$

*Proof.* We only need to calculate the terms

$$\mathbb{E}\left[\sum_{i=1}^d \tilde{g}_{t,i}^2 x_{t,i}^{3/2}\right] .$$

Proceeding as in (11.4), we obtain

$$\mathbb{E}\left[\sum_{i=1}^{d} \tilde{g}_{t,i}^{2} x_{t,i}^{3/2}\right] = \mathbb{E}\left[\mathbb{E}\left[\sum_{i=1}^{d} x_{t,i}^{3/2} \tilde{g}_{t,i}^{2} \middle| A_{1}, \dots, A_{t-1}\right]\right] = \mathbb{E}\left[\sum_{i=1}^{d} x_{t,i}^{3/2} \frac{g_{t,i}^{2}}{x_{t,i}^{2}} x_{t,i}\right] = \mathbb{E}\left[\sum_{i=1}^{d} g_{t,i}^{2} \sqrt{x_{t,i}}\right] \\
\leq \mathbb{E}\left[\sqrt{\sum_{i=1}^{d} g_{t,i}^{2}} \sqrt{\sum_{i=1}^{d} g_{t,i}^{2} x_{t,i}}\right] \leq L_{\infty}^{2} \sqrt{d} .$$

Choosing  $\eta \propto \frac{1}{L_{\infty}\sqrt{T}}$ , we finally obtain an expected regret of  $\mathcal{O}(L_{\infty}\sqrt{dT})$  as  $T\to\infty$ , that can be proved to be

There is one last thing: How do we compute the predictions of this algorithm? In each step, we have to solve a constrained optimization problem. So, we can write the corresponding Lagrangian:

$$L(\boldsymbol{x},\beta) = \sum_{i=1}^{d} \left( \eta \tilde{g}_{t,i} + \frac{q}{1-q} x_{t,i}^{q-1} \right) x_i - \frac{1}{1-q} \sum_{i=1}^{d} x_i^q + \beta \left( \sum_{i=1}^{d} x_i - 1 \right) .$$

From the KKT conditions, we have

$$x_{t+1,i} = \left[ \frac{1-q}{q} \left( \beta + \frac{q}{1-q} x_{t,i}^{q-1} + \eta \tilde{g}_{t,i} \right) \right]^{\frac{1}{q-1}}.$$

and we also know that  $\sum_{i=1}^{d} x_{t+1,i} = 1$ . So, we have a 1-dimensional problem in  $\beta$  that must be solved in each round.

# 11.2 Stochastic Bandits

We will now consider the *stochastic bandit* setting. Here, each arm is associated with an unknown probability distribution. At each time step, the algorithm selects one arm  $A_t$  and it receives a loss (or reward)  $g_{t,A_t}$  drawn i.i.d. from the distribution of the arm  $A_t$ . We focus on minimizing the *pseudo-regret*, that is the regret with respect to the optimal action in expectation, rather than the optimal action on the sequence of realized losses:

$$\operatorname{Regret}_T := \mathbb{E}\left[\sum_{t=1}^T g_{t,A_t}\right] - \min_{i=1,\dots,d} \mathbb{E}\left[\sum_{t=1}^T g_{t,i}\right] = \mathbb{E}\left[\sum_{t=1}^T g_{t,A_t}\right] - \min_{i=1,\dots,d} \mu_i,$$

where we denoted by  $\mu_i$  the expectation of the distribution associated with the arm i.

**Remark 11.4.** The usual notation in the stochastic bandit literature is to consider rewards instead of losses. Instead, to keep our notation coherent with the OCO literature, we will consider losses. The two things are completely equivalent up to a multiplication by -1.

Before presenting our first algorithm for stochastic bandits, we will introduce some basic notions on concentration inequalities that will be useful in our definitions and proofs.

## 11.2.1 Concentration Inequalities Bits

Suppose that  $X_1, X_2, \ldots, X_n$  is a sequence of independent and identically distributed random variables and with mean  $\mu = \mathbb{E}[X_1]$  and variance  $\sigma = \operatorname{Var}[X_1]$ . Having observed  $X_1, X_2, \ldots, X_n$  we would like to estimate the common mean  $\mu$ . The most natural estimator is the *empirical mean* 

$$\hat{\mu} = \frac{1}{n} \sum_{i=1}^{n} X_i .$$

Linearity of expectation shows that  $\mathbb{E}[\hat{\mu}] = \mu$ , which means that  $\hat{\mu}$  is an *unbiased estimator* of  $\mu$ . Yet,  $\hat{\mu}$  is a random variable itself. So, can we quantify how far  $\hat{\mu}$  will be from  $\mu$ ?

We could use Chebyshev's inequality to upper bound the probability that  $\hat{\mu}$  is far from  $\mu$ :

$$\mathbb{P}\{|\hat{\mu} - \mu| \ge \epsilon\} \le \frac{\operatorname{Var}[\hat{\mu}]}{\epsilon^2} .$$

Using the fact that  $Var[\hat{\mu}] = \frac{\sigma^2}{n}$ , we have that

$$\mathbb{P}\{|\hat{\mu} - \mu| \ge \epsilon\} \le \frac{\sigma^2}{n\epsilon^2} .$$

So, we can expect the probability of having a "bad" estimate to go to zero as one over the number of samples in our empirical mean. Is this the best we can get? To understand what we can hope for, let's take a look at the central limit theorem.

We know that, defining  $S_n = \sum_{t=1}^n (X_i - \mu)$ ,  $\frac{S_n}{\sqrt{n\sigma^2}} \to N(0,1)$ , the standard Gaussian distribution, as n goes to infinity. This means that

$$\mathbb{P}\{\hat{\mu} - \mu \ge \epsilon\} = \mathbb{P}\{S_n \ge n\epsilon\} = \mathbb{P}\left\{\frac{S_n}{\sqrt{n\sigma^2}} \ge \sqrt{\frac{n}{\sigma^2}}\epsilon\right\} \approx \int_{\epsilon\sqrt{\frac{n}{2}}}^{\infty} \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{x^2}{2}\right) dx,$$

where the approximation comes from the central limit theorem. The integral cannot be calculated with a closed form, but we can easily upper bound it. Indeed, for a > 0, we have

$$\int_{a}^{\infty} \exp\left(-\frac{x^2}{2}\right) dx = \int_{a}^{\infty} \frac{x}{x} \exp\left(-\frac{x^2}{2}\right) dx \le \frac{1}{a} \int_{a}^{\infty} x \exp\left(-\frac{x^2}{2}\right) dx = \frac{1}{a} \exp\left(-\frac{a^2}{2}\right).$$

Hence, we have

$$\mathbb{P}\{\hat{\mu} - \mu \ge \epsilon\} \lessapprox \sqrt{\frac{\sigma^2}{2\pi\epsilon^2 n}} \exp\left(-\frac{n\epsilon^2}{2\sigma^2}\right) . \tag{11.5}$$

This is better than what we got with Chebyshev's inequality and we would like to obtain an exact bound with a similar asymptotic rate. To do that, we will focus our attention on *subgaussian* random variables.

**Definition 11.5** (Subgaussian Random Variable). We say that a random variable is  $\sigma$ -subgaussian if for all  $\lambda \in \mathbb{R}$  we have that  $\mathbb{E}[\exp(\lambda X)] \leq \exp(\lambda^2 \sigma^2/2)$ .

**Example 11.6.** The following random variable are subgaussian:

- If X is Gaussian with mean zero and variance  $\sigma^2$ , then X is  $\sigma$ -subgaussian.
- If X has mean zero and  $\mathcal{X} \in [a,b]$  almost surely, then X is (b-a)/2-subgaussian.

We have the following properties for subgaussian random variables.

**Lemma 11.7** ([Lattimore and Szepesvári, 2020, Lemma 5.4]). Assume that  $X_1$  and  $X_2$  are independent and  $\sigma_1$ -subgaussian and  $\sigma_2$ -subgaussian respectively. Then,

- (a)  $\mathbb{E}[X_1] = 0$  and  $\operatorname{Var}[X_1] \leq \sigma_1^2$ .
- (b)  $cX_1$  is  $|c|\sigma_1$ -subgaussian.
- (c)  $X_1 + X_2$  is  $\sqrt{\sigma_1^2 + \sigma_2^2}$ -subgaussian.

Subgaussians random variables behaves like Gaussian random variables, in the sense that their tail probabilities are upper bounded by the ones of a Gaussian of variance  $\sigma^2$ . To prove it, let's first state the Markov's inequality.

**Theorem 11.8** (Markov's inequality). For a non-negative random variable X and  $\epsilon > 0$ , we have that  $\mathbb{P}\{X \ge \epsilon\} \le \underline{\mathbb{E}[X]}$ .

With Markov's inequality, we can now formalize the above statement on subgaussian random variables.

**Theorem 11.9.** If a random variable is  $\sigma$ -subgaussian, then  $\mathbb{P}\{X \geq \epsilon\} \leq \exp\left(-\frac{\epsilon^2}{2\sigma^2}\right)$ .

*Proof.* For any  $\lambda > 0$ , we have

$$\mathbb{P}\{X \geq \epsilon\} = \mathbb{P}\{\exp(\lambda X) \geq \exp(\lambda \epsilon)\} \leq \frac{\mathbb{E}[\exp(\lambda X)]}{\exp(\lambda \epsilon)} \leq \exp(\lambda^2 \sigma^2 / 2 - \lambda \epsilon) \;.$$

Minimizing the right hand side of the inequality w.r.t.  $\lambda$ , we have the stated result.

An easy consequence of the above theorem is that the empirical average of subgaussian random variables concentrates around its expectation, with the same asymptotic rate in (11.5).

**Corollary 11.10.** Assume that  $X_i - \mu$  are independent,  $\sigma$ -subgaussian random variables. Then, for any  $\epsilon \geq 0$ , we have

$$\mathbb{P}\left\{\hat{\mu} \geq \mu + \epsilon\right\} \leq \exp\left(-\frac{n\epsilon^2}{2\sigma^2}\right) \qquad \qquad \text{and} \qquad \qquad \mathbb{P}\left\{\hat{\mu} \leq \mu - \epsilon\right\} \leq \exp\left(-\frac{n\epsilon^2}{2\sigma^2}\right),$$

where  $\hat{\mu} = \frac{1}{n} \sum_{i=1}^{n} X_i$ .

Equating the upper bounds on the r.h.s. of the inequalities in the Corollary to  $\delta$ , we have the equivalent statement that, with probability at least  $1-2\delta$ , we have

$$\mu \in \left[ \hat{\mu} - \sqrt{\frac{2\sigma^2 \ln \frac{1}{\delta}}{n}}, \hat{\mu} + \sqrt{\frac{2\sigma^2 \ln \frac{1}{\delta}}{n}} \right].$$

# Algorithm 11.4 Explore-Then-Commit Algorithm

Require: 
$$T, m \in \mathbb{N}, 1 \le m \le \frac{T}{d}$$
  
1:  $S_{0,i} = 0, \hat{\mu}_{0,i} = 0, i = 1, \dots, d$   
2: **for**  $t = 1$  **to**  $T$  **do**  
3: Choose  $A_t = \begin{cases} (t \mod d) + 1, & t \le dm \\ \operatorname{argmin}_i \hat{\mu}_{dm,i}, & t > dm \end{cases}$   
4: Observe  $g_{t,A_t}$  and pay it  
5:  $S_{t,i} = S_{t-1,i} + \mathbf{1}[A_t = i]$   
6:  $\hat{\mu}_{t,i} = \frac{1}{S_{t,i}} \sum_{j=1}^{t} g_{j,A_j} \mathbf{1}[A_j = i], i = 1, \dots, d$ 

# 11.2.2 Explore-Then-Commit Algorithm

We are now ready to present the most natural algorithm for the stochastic bandit setting, called Explore-Then-Commit (ETC) algorithm. That is, we first identify the best arm over md exploration rounds and then we commit to it. This algorithm is summarized in Algorithm 11.4.

In the following, we will denote by  $S_{t,i} = \sum_{j=1}^{t} \mathbf{1}[A_j = i]$ , that is the number of times that the arm i was pulled in the first t rounds.

Define by  $\mu^*$  the expected loss of the arm with the smallest expectation, that is  $\min_{i=1,\dots,d} \mu_i$ . Critical quantities in our analysis will be the gaps,  $\Delta_i := \mu_i - \mu^*$  for  $i=1,\dots,d$ , that measure the expected difference in losses between the arms and the optimal one. In particular, we can decompose the regret as a sum over the arms of the expected number of times we pull an arm multiplied by its gap.

**Lemma 11.11.** For any policy of selection of the arms, the regret is upper bounded by

$$\operatorname{Regret}_T = \sum_{i=1}^d \mathbb{E}[S_{T,i}] \Delta_i$$
.

Proof. Observe that

$$\sum_{t=1}^{T} g_{t,A_t} = \sum_{t=1}^{T} \sum_{i=1}^{d} g_{t,i} \mathbf{1}[A_t = i] .$$

Hence,

$$\operatorname{Regret}_{T} = \mathbb{E}\left[\sum_{t=1}^{T} g_{t,A_{t}}\right] - T\mu^{*} = \mathbb{E}\left[\sum_{t=1}^{T} (g_{t,A_{t}} - \mu^{*})\right] = \sum_{i=1}^{d} \sum_{t=1}^{T} \mathbb{E}[\mathbf{1}[A_{t} = i](g_{t,i} - \mu^{*})]$$

$$= \sum_{i=1}^{d} \sum_{t=1}^{T} \mathbb{E}[\mathbb{E}[\mathbf{1}[A_{t} = i](g_{t,i} - \mu^{*})|A_{t}]] = \sum_{i=1}^{d} \sum_{t=1}^{T} \mathbb{E}[\mathbf{1}[A_{t} = i]\mathbb{E}[g_{t,i} - \mu^{*}|A_{t}]]$$

$$= \sum_{i=1}^{d} \sum_{t=1}^{T} \mathbb{E}[\mathbf{1}[A_{t} = i]](\mu_{i} - \mu^{*}).$$

The above Lemma quantifies the intuition that in order to have a small regret we have to select the suboptimal arms less often then the best one.

We are now ready to prove the regret guarantee of the ETC algorithm.

**Theorem 11.12.** Assume that the losses of the arms minus their expectations are 1-subgaussian and  $1 \le m \le T/d$ . Then, ETC guarantees a regret of

$$\operatorname{Regret}_{T} \leq m \sum_{i=1}^{d} \Delta_{i} + (T - md) \sum_{i=1}^{d} \Delta_{i} \exp\left(-\frac{m\Delta_{i}^{2}}{4}\right).$$

*Proof.* Without loss of generality, let's assume that the optimal arm is the first one. So, for  $i \neq 1$ , we have

$$\mathbb{E}[S_{T,i}] = \sum_{t=1}^{T} \mathbb{E}[\mathbf{1}[A_t = i]] = m + (T - md) \mathbb{P}\left\{\hat{\mu}_{md,i} \le \min_{j \ne i} \hat{\mu}_{md,j}\right\}$$

$$\le m + (T - md) \mathbb{P}\left\{\hat{\mu}_{md,i} \le \hat{\mu}_{md,1}\right\}$$

$$= m + (T - md) \mathbb{P}\left\{\hat{\mu}_{md,1} - \mu_1 - (\hat{\mu}_{md,i} - \mu_i) \ge \Delta_i\right\}.$$

From Lemma 11.7, we have that  $\hat{\mu}_{md,i} - \mu_i - (\hat{\mu}_{md,1} - \mu_1)$  is  $\sqrt{2/m}$ -subgaussian. So, from Theorem 11.9, we have

$$\mathbb{P}\left\{\hat{\mu}_{md,1} - \mu_1 - (\hat{\mu}_{md,i} - \mu_i) \ge \Delta_i\right\} \le \exp\left(-\frac{m\Delta_i^2}{4}\right).$$

Using Lemma 11.11 finishes the proof.

The bound shows the trade-off between exploration and exploitation: if m is too big, we pay too much during the exploration phase (first term in the bound). On the other hand, if m is small, the probability to select a suboptimal arm increases (second term in the bound). Knowing all the gaps  $\Delta_i$ , it is possible to choose m that minimizes the bound.

For example, in that case that d = 2, the regret is upper bounded by

$$m\Delta + (T - 2m)\Delta \exp\left(-m\frac{\Delta^2}{4}\right) \le m\Delta + T\Delta \exp\left(-m\frac{\Delta^2}{4}\right)$$

that is minimized by

$$m = \frac{4}{\Delta^2} \ln \frac{T\Delta^2}{4} \ .$$

Remembering that m must be a natural number we can choose

$$m = \max\left(\left\lceil\frac{4}{\Delta^2}\ln\frac{T\Delta^2}{4}\right\rceil, 1\right) \, .$$

When  $\frac{T\Delta^2}{4} \leq 1$ , we select m=1. So, we have  $\Delta+(T-2)\Delta \leq T\Delta \leq \frac{4}{\Delta}$ . Hence, the regret is upper bounded by

$$\min\left(\Delta T, \frac{4}{\Delta}\left(1 + \max\left(\ln\frac{T\Delta^2}{4}, 0\right)\right) + \Delta\right) = \mathcal{O}\left(\frac{\ln T}{\Delta}\right) \text{ as } T \text{ goes to infinity.}$$

The main drawback of this algorithm is that its optimal tuning depends on the gaps  $\Delta_i$ . Assuming the knowledge of the gaps accounts to make the stochastic bandit problem completely trivial. However, its tuned regret bound gives us a baseline to which compare other bandit algorithms. In particular, in the next section we will present an algorithm that achieves the same asymptotic regret without any knowledge of the gaps.

## 11.2.3 Upper Confidence Bound Algorithm

The ETC algorithm has the disadvantage of requiring the knowledge of the gaps to tune the exploration phase. Moreover, it solves the exploration vs. exploitation trade-off in a clunky way. It would be better to have an algorithm that smoothly mixes exploration and exploitation *in a data-dependent way*. So, we now describe an optimal and adaptive strategy called Upper Confidence Bound (UCB) algorithm. It employs the principle of *optimism in the face of uncertainty*, to select in each round the arm that has the *potential to be the best one*.

UCB works keeping an estimate of the expected loss of each arm and also a confidence interval at a certain probability. Roughly speaking, we have that with probability at least  $1-\delta$ 

$$\mu_i \in \left[\hat{\mu}_i - \sqrt{\frac{2\ln\frac{1}{\delta}}{S_{t-1,i}}}, \hat{\mu}_i\right],$$

### **Algorithm 11.5** Upper Confidence Bound Algorithm

**Require:**  $\alpha > 2, T \in \mathbb{N}$ 

1: 
$$S_{0,i} = 0, \hat{\mu}_{0,i} = 0, i = 1, \dots, d$$

2: for t = 1 to T do

2: **lor** 
$$t=1$$
 **to**  $T$  **do**
3: Choose  $A_t = \operatorname{argmin}_{i=1,\dots,d} \begin{cases} \hat{\mu}_{t-1,i} - \sqrt{\frac{2\alpha \ln t}{S_{t-1,i}}}, & \text{if } S_{t-1,i} \neq 0 \\ -\infty, & \text{otherwise} \end{cases}$ 

Observe  $g_{t,A_t}$  and pay it

5: 
$$S_{t,i} = S_{t-1,i} + \mathbf{1}[A_t = i]$$

4: Observe 
$$g_{t,A_t}$$
 and pay it  
5:  $S_{t,i} = S_{t-1,i} + \mathbf{1}[A_t = i]$   
6:  $\hat{\mu}_{t,i} = \frac{1}{S_{t,i}} \sum_{j:A_j=i}^t g_{j,A_j}, \ i = 1, \dots, d$   
7: **end for**

where the "roughly" comes from the fact that  $S_{t-1,i}$  is a random variable itself. Then, UCB will query the arm with the smallest lower bound, that is the one that could potentially have the smallest expected loss. The regret bound below shows that this strategy automatically balances exploration (given by the use of the optimistic estimates through the confidence intervals) and exploitation (when the confidence intervals are small enough so that we query the arm with the smallest empirical mean).

Remark 11.13. The name "Upper Confidence Bound" comes from the fact that traditionally stochastic bandits are defined over rewards, rather than losses. So, in our case we actually use the lower confidence bound in the algorithm. However, to avoid confusion with the literature, we still call it Upper Confidence Bound algorithm.

The proof works by proving that, once we have queried a suboptimal arm enough times, we will pull it again only if its confidence interval or the one around the best arm do not contain the true means. In turn, the probability that the confidence intervals are wrong is small because we use concentration inequalities to construct them. Moreover, a delicate point is to deal with the fact that the number of times we pull an arm is a random variable, making the application of the concentration inequality delicate. We go around it considering the worst number of pulls and taking a union bound on it.

The algorithm is summarized in Algorithm 11.5 and we can prove the following regret bound.

**Theorem 11.14.** Assume that the losses of the arms minus their expectations are 1-subgaussian and let  $\alpha > 2$ . Then, UCB guarantees a regret of

$$\operatorname{Regret}_T \leq \frac{\alpha}{\alpha - 2} \sum_{i=1}^d \Delta_i + \sum_{i: \Delta_i > 0} \frac{8\alpha \ln T}{\Delta_i} .$$

*Proof.* We analyze one arm at the time. Also, without loss of generality, assume that the optimal arm is the first one. For arm i, we want to prove that  $\mathbb{E}[S_{T,i}] \leq \frac{8\alpha \ln T}{\Delta_i^2} + \frac{\alpha}{\alpha - 2}$ .

The proof is based on the fact that once I have sampled a suboptimal arm enough times, the probability to select it again becomes small.

Let  $t^*$  the biggest time index such that  $S_{t^*-1,i} \leq \frac{8\alpha \ln T}{\Delta_i^2}$ . If  $t^* = T$ , then the statement above is true. Hence, we can safely assume  $t^* < T$ . Now, for  $t > t^*$ , we have

$$S_{t-1,i} > \frac{8\alpha \ln T}{\Delta_i^2} \ . \tag{11.6}$$

Consider  $t > t^*$  and such that  $A_t = i$ , then we claim that at least one of the two following equations must be true:

$$\hat{\mu}_{t-1,1} - \sqrt{\frac{2\alpha \ln t}{S_{t-1,1}}} \ge \mu_1,\tag{11.7}$$

$$\hat{\mu}_{t-1,i} + \sqrt{\frac{2\alpha \ln t}{S_{t-1,i}}} < \mu_i . \tag{11.8}$$

If the first one is true, the confidence interval around our estimate of the expectation of the optimal arm does not contain  $\mu_1$ . On the other hand, if the second one is true the confidence interval around our estimate of the expectation  $\mu_i$  does not contain  $\mu_i$ . So, we claim that if  $t > t^*$  and we selected the suboptimal arm i, then at least one of these two bad events happened.

Let's prove the claim by contradiction: if both the inequalities above are false,  $t > t^*$ , and  $A_t = i$ , we have

$$\begin{split} \hat{\mu}_{t-1,1} - \sqrt{\frac{2\alpha \ln t}{S_{t-1,1}}} < \mu_1 & \quad \text{((11.7) false)} \\ &= \mu_i - \Delta_i \\ &< \mu_i - 2\sqrt{\frac{2\alpha \ln T}{S_{t-1,i}}} & \quad \text{(for (11.6))} \\ &\leq \mu_i - 2\sqrt{\frac{2\alpha \ln t}{S_{t-1,i}}} \\ &\leq \hat{\mu}_{t-1,i} - \sqrt{\frac{2\alpha \ln t}{S_{t-1,i}}} & \quad \text{((11.8) false),} \end{split}$$

that, by the selection strategy of the algorithm, would imply  $A_t \neq i$ .

Note that  $S_{t^\star,i} \leq \frac{8\alpha \ln T}{\Delta_i^2} + 1$ . Hence, we have

$$\begin{split} S_{T,i} &= S_{t^{\star},i} + \sum_{t=t^{\star}+1}^{T} \mathbf{1}[A_t = i] \\ &\leq \frac{8\alpha \ln T}{\Delta_i^2} + 1 + \sum_{t=t^{\star}+1}^{T} \mathbf{1}[(11.7) \text{ or } (11.8) \text{ true}] \\ &\leq \frac{8\alpha \ln T}{\Delta_i^2} + 1 + \sum_{t=1}^{\infty} \mathbf{1}[(11.7) \text{ or } (11.8) \text{ true}] \\ &\leq \frac{8\alpha \ln T}{\Delta_i^2} + 1 + \sum_{t=1}^{\infty} \left(\mathbf{1}[(11.7) \text{ true}] + \mathbf{1}[(11.8) \text{ true}]\right) \;. \end{split}$$

Taking the expectation to both sides, we have

$$\mathbb{E}[S_{T,i}] \leq \frac{8\alpha \ln T}{\Delta_i^2} + 1 + \sum_{t=1}^{\infty} \left( \mathbb{P}\{(11.7) \text{ true}\} + \mathbb{P}\{(11.8) \text{ true}\} \right) .$$

Now, we upper bound the probabilities in the sum. Given that the losses on the arms are i.i.d. and using the union bound, we have

$$\mathbb{P}\left\{\hat{\mu}_{t-1,1} - \sqrt{\frac{2\alpha \ln t}{S_{t-1,1}}} \ge \mu_1\right\} \le \mathbb{P}\left\{\max_{s=1,\dots,t-1} \frac{1}{s} \sum_{j=1}^{s} g_{j,1} - \sqrt{\frac{2\alpha \ln t}{s}} \ge \mu_1\right\} \\
= \mathbb{P}\left\{\bigcup_{s=1}^{t-1} \left\{\frac{1}{s} \sum_{j=1}^{s} g_{j,1} - \sqrt{\frac{2\alpha \ln t}{s}} \ge \mu_1\right\}\right\}.$$

Hence, using Corollary 11.10 we have

$$\mathbb{P}\{(11.7) \text{ true}\} \leq \sum_{s=1}^{t-1} \mathbb{P}\left\{\frac{1}{s} \sum_{j=1}^{s} g_{j,1} - \sqrt{\frac{2\alpha \ln t}{s}} \geq \mu_1\right\} \qquad \text{(union bound)}$$

$$\leq \sum_{s=1}^{t-1} t^{-\alpha} = (t-1)t^{-\alpha} .$$

Given that the same bound holds for  $\mathbb{P}\{(11.8) \text{ true}\}$ , we have

$$\mathbb{E}\left[S_{T,i}\right] \le \frac{8\alpha \ln T}{\Delta_i^2} + 1 + \sum_{t=1}^{\infty} 2(t-1)t^{-\alpha} \le \frac{8\alpha \ln T}{\Delta_i^2} + 1 + \sum_{t=2}^{\infty} 2t^{1-\alpha} \le \frac{8\alpha \ln T}{\Delta_i^2} + 1 + 2\int_1^{\infty} x^{1-\alpha} \, \mathrm{d}x$$

$$= \frac{8\alpha \ln T}{\Delta_i^2} + \frac{\alpha}{\alpha - 2} \, .$$

Using the decomposition of the regret in Lemma 11.11,  $\operatorname{Regret}_T = \sum_{i=1}^d \Delta_i \mathbb{E}[S_{T,i}]$ , we have the stated bound.

The bound above can become meaningless if the gaps are too small. So, here we prove another bound that does not depend on the inverse of the gaps.

**Theorem 11.15.** Assume that the losses of the arms minus their expectations are 1-subgaussian and let  $\alpha > 2$ . Then, UCB guarantees a regret of

$$\operatorname{Regret}_T \le 4\sqrt{2\alpha dT \ln T} + \frac{\alpha}{\alpha - 2} \sum_{i=1}^d \Delta_i$$
.

*Proof.* Let  $\beta > 0$  be some value to be tuned subsequently and recall from the proof of Theorem 11.14 that for each suboptimal arm i we can bound

$$\mathbb{E}[S_{T,i}] \le \frac{\alpha}{\alpha - 2} + \frac{8\alpha \ln T}{\Delta_i^2} \ .$$

Hence, using the regret decomposition in Lemma 11.11, we have

$$\operatorname{Regret}_{T} = \sum_{i:\Delta_{i} < \beta} \Delta_{i} \mathbb{E}[S_{T,i}] + \sum_{i:\Delta_{i} \geq \beta} \Delta_{i} \mathbb{E}[S_{T,i}]$$

$$\leq T\beta + \sum_{i:\Delta_{i} \geq \beta} \Delta_{i} \mathbb{E}[S_{T,i}]$$

$$\leq T\beta + \sum_{i:\Delta_{i} \geq \beta} \left(\Delta_{i} \frac{\alpha}{\alpha - 2} + \frac{8\alpha \ln T}{\Delta_{i}}\right)$$

$$\leq T\beta + \frac{\alpha}{\alpha - 2} \sum_{i=1}^{d} \Delta_{i} + \frac{8\alpha d \ln T}{\beta}.$$

Choosing  $\beta = \sqrt{\frac{8\alpha d \ln T}{T}}$ , we have the stated bound.

**Remark 11.16.** Note that while the UCB algorithm is considered parameter-free, we still have to know the subgaussianity of the arms. While this can be easily upper bounded for stochastic arms with bounded support, it is unclear how to do it without any prior knowledge on the distribution of the arms.

It is possible to prove that the UCB algorithm is asymptotically optimal, in the sense of the following Theorem.

**Theorem 11.17** ([Bubeck and Cesa-Bianchi, 2012, Theorem 2.2]). Consider a strategy that satisfies  $\mathbb{E}[S_{T,i}] = o(T^a)$  as  $T \to \infty$  for any set of Bernoulli loss distributions, any arm i with  $\Delta_i > 0$  and any a > 0. Then, for any set of Bernoulli loss distributions, the following holds

$$\liminf_{T \to +\infty} \frac{\mathrm{Regret}_T}{\ln T} \geq \sum_{i:\Delta_i} \frac{1}{2\Delta_i} \; .$$

# 11.3 History Bits

The algorithm in Algorithm 11.1 is from Cesa-Bianchi and Lugosi [2006, Theorem 6.9]. The Exp3 algorithm was proposed in Auer et al. [2002b] and it used a small exploration rate to achieve the same regret we proved. The observation that the exploration in Exp3 can be removed completely is from Stoltz [2005].

The INF algorithm was proposed by Audibert and Bubeck [2009] and re-casted as an OMD procedure in Audibert et al. [2011]. The connection with the Tsallis entropy was done in Abernethy et al. [2015]. The specific proof presented here is new and it builds on the proof by Abernethy et al. [2015]. Note that Abernethy et al. [2015] proved the same regret bound for a FTRL procedure over the stochastic estimates of the losses (that they call Gradient-Based Prediction Algorithm), while here we proved it using a OMD procedure.

The ETC algorithm goes back to Robbins [1952], even if Robbins proposed what is now called epoch-greedy [Langford and Zhang, 2008]. For more history on ETC, take a look at chapter 6 in Lattimore and Szepesvári [2020]. The proofs presented here are from Lattimore and Szepesvári [2020] as well.

The use of confidence bounds and the idea of optimism first appeared in the work by Lai and Robbins [1985]. The first version of UCB is by Lai [1987]. The version of UCB I presented is by Auer et al. [2002a] under the name UCB1. Note that, rather than considering 1-subgaussian environments, Auer et al. [2002a] considers bandits where the rewards are confined to the [0, 1] interval. The proof of Theorem 11.14 is a minor variation of the one of Theorem 2.1 in Bubeck and Cesa-Bianchi [2012], which also popularized the subgaussian setup. Theorem 11.15 is from Bubeck and Cesa-Bianchi [2012].

# 11.4 Exercises

**Problem 11.1.** Design and analyse an FTRL version of Exp3 and Poly-INF/OMD with Tsallis entropy with timevarying non-decreasing regularizers.

**Problem 11.2.** Consider OMD with Tsallis entropy and prove that the update is invariant to any constant  $a \in \mathbb{R}$  added to all the coordinates of the loss vector  $\mathbf{g}_t$ .

**Problem 11.3.** Prove a similar regret bound to the one in Theorem 11.15 for an optimally tuned Explore-Then-Commit algorithm.

# Chapter 12

# Saddle-Point Optimization and OCO Algorithms

In this chapter, we talk about solving saddle point problems with online convex optimization (OCO) algorithms, and the connection with game theory.

# 12.1 Saddle-Point Problems

We want to solve the following saddle point problem

$$\inf_{\boldsymbol{x} \in \mathcal{X}} \sup_{\boldsymbol{y} \in \mathcal{Y}} f(\boldsymbol{x}, \boldsymbol{y}). \tag{12.1}$$

Let's say from the beginning that we need  $\inf$  and  $\sup$  rather than  $\min$  and  $\max$  because the minimum or maximum might not exist. Every time we know for sure the  $\inf$ sup are attained, we can substitute them with  $\min$ sup.

While for the minimization of functions is clear what it means to solve it, it might not be immediate to see what is the meaning of "solving" the saddle point problem in (12.1). It turns out that the proper notion we are looking for is the one of saddle point.

**Definition 12.1** (Saddle Point). Let  $\mathcal{X} \subseteq \mathbb{R}^n$ ,  $\mathcal{Y} \subseteq \mathbb{R}^m$ , and  $f : \mathcal{X} \times \mathcal{Y} \to \mathbb{R}$ . A point  $(\mathbf{x}^*, \mathbf{y}^*) \in \mathcal{X} \times \mathcal{Y}$  is a saddle point of f in  $\mathcal{X} \times \mathcal{Y}$  if

$$f(x^*, y) \le f(x^*, y^*) \le f(x, y^*), \quad \forall x \in \mathcal{X}, y \in \mathcal{Y}.$$

We will now state conditions under which there *exists* a saddle point that solves (12.1). First, we need an easy lemma.

**Lemma 12.2.** Let f is a function from a non-empty product set  $\mathcal{X} \times \mathcal{Y}$  to  $\mathbb{R}$ . Then,

$$\inf_{\boldsymbol{x} \in \mathcal{X}} \sup_{\boldsymbol{y} \in \mathcal{Y}} \ f(\boldsymbol{x}, \boldsymbol{y}) \geq \sup_{\boldsymbol{y} \in \mathcal{Y}} \inf_{\boldsymbol{x} \in \mathcal{X}} \ f(\boldsymbol{x}, \boldsymbol{y}) \ .$$

*Proof.* For any  $x' \in \mathcal{X}$  and  $y \in \mathcal{Y}$  we have that  $f(x', y) \ge \inf_{x \in \mathcal{X}} f(x, y)$ . This implies that  $\sup_{y \in \mathcal{Y}} f(x', y) \ge \sup_{y \in \mathcal{Y}} \inf_{x \in \mathcal{X}} f(x, y)$  for all  $x' \in \mathcal{X}$  that gives the stated inequality.

We can now state the following theorem.

**Theorem 12.3.** Let f any function from a non-empty product set  $\mathcal{X} \times \mathcal{Y}$  to  $\mathbb{R}$ . A point  $(\mathbf{x}^*, \mathbf{y}^*)$  is a saddle point of f if and only if the supremum in

$$\sup_{\mathbf{y} \in \mathcal{Y}} \inf_{\mathbf{x} \in \mathcal{X}} f(\mathbf{x}, \mathbf{y}) \tag{12.2}$$

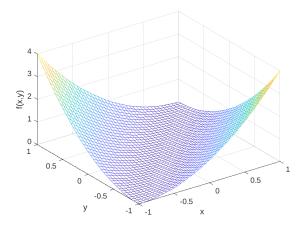

Figure 12.1: The function  $f(x,y) = (x-y)^2$  does not have a saddle point.

is attained at  $y^*$ , the infimum in

$$\inf_{\mathbf{x} \in \mathcal{X}} \sup_{\mathbf{y} \in \mathcal{Y}} f(\mathbf{x}, \mathbf{y}) \tag{12.3}$$

is at  $x^*$ , and these two expressions are equal.

*Proof.* If  $(x^*, y^*)$  is a saddle point, then we have

$$\begin{split} f(\boldsymbol{x}^{\star}, \boldsymbol{y}^{\star}) &= \inf_{\boldsymbol{x} \in \mathcal{X}} \ f(\boldsymbol{x}, \boldsymbol{y}^{\star}) \leq \sup_{\boldsymbol{y} \in \mathcal{Y}} \inf_{\boldsymbol{x} \in \mathcal{X}} \ f(\boldsymbol{x}, \boldsymbol{y}) \\ f(\boldsymbol{x}^{\star}, \boldsymbol{y}^{\star}) &= \sup_{\boldsymbol{y} \in \mathcal{Y}} \ f(\boldsymbol{x}^{\star}, \boldsymbol{y}) \geq \inf_{\boldsymbol{x} \in \mathcal{X}} \sup_{\boldsymbol{y} \in \mathcal{Y}} \ f(\boldsymbol{x}, \boldsymbol{y}) \ . \end{split}$$

From Lemma 12.2, we have that these quantities must be equal, so that the three conditions in the theorem are satisfied. For the other direction, if the conditions are satisfied, then we have

$$f(\boldsymbol{x}^{\star},\boldsymbol{y}^{\star}) \leq \sup_{\boldsymbol{y} \in \mathcal{Y}} \ f(\boldsymbol{x}^{\star},\boldsymbol{y}) = \inf_{\boldsymbol{x} \in \mathcal{X}} \ f(\boldsymbol{x},\boldsymbol{y}^{\star}) \leq f(\boldsymbol{x}^{\star},\boldsymbol{y}^{\star}) \ .$$

Hence,  $(x^*, y^*)$  is a saddle point.

**Remark 12.4.** The above theorem implies that the set of saddle points, when nonempty, is the Cartesian product  $\mathcal{X}^* \times \mathcal{Y}^*$ , where  $\mathcal{X}^*$  and  $\mathcal{Y}^*$  are the sets of optimal solutions of the optimization problems (12.2) and (12.3), respectively. In other words,  $\mathbf{x}^*$  and  $\mathbf{y}^*$  can be independently chosen from the sets  $\mathcal{X}^*$  and  $\mathcal{Y}^*$ , respectively, to form a saddle point.

Remark 12.5. The above theorem tells a surprising thing: If a saddle point exists, then there might be multiple ones, and all of them must have the same minimax value. This might seem surprising, but it is due to the fact that the definition of saddle point is a global and not a local property. Moreover, if the inf sup and sup inf problem have different values, no saddle point exists.

**Remark 12.6.** Consider the case that the value of the inf sup and sup inf are different. If your favorite optimization procedure to find the solution of a saddle point problem does not distinguish between a inf sup and sup inf formulation, then it cannot be correct!

Let's show a couple of examples that show that the conditions above are indeed necessary.

**Example 12.7.** Let 
$$f(x,y) = (x-y)^2$$
,  $\mathcal{X} = [-1,1]$ , and  $\mathcal{Y} = [-1,1]$ . Then, we have

$$\inf_{x \in \mathcal{X}} \sup_{y \in \mathcal{Y}} (x - y)^2 = \inf_{x \in \mathcal{X}} (1 + |x|)^2 = 1,$$

while

$$\sup_{y \in \mathcal{Y}} \inf_{x \in \mathcal{X}} (x - y)^2 = \sup_{y \in \mathcal{Y}} 0 = 0.$$

Indeed, from Figure 12.1 we can see that there is no saddle point.

**Example 12.8.** Let f(x,y) = xy,  $\mathcal{X} = (0,1]$ , and  $\mathcal{Y} = (0,1]$ . Then, we have

$$\inf_{x \in \mathcal{X}} \sup_{y \in \mathcal{Y}} xy = \inf_{x \in \mathcal{X}} x = 0$$

and

$$\sup_{y \in \mathcal{Y}} \inf_{x \in \mathcal{X}} xy = 0.$$

Here, even if inf sup is equal to sup inf, the saddle point does not exist because the inf in the first expression is not attained in a point of X.

Theorem 12.3 also tells us that in order to find a saddle point of a function f, we need to find the minimizer in x of  $\sup_{y \in \mathcal{Y}} f(x, y)$  and the maximizer in y of  $\inf_{x \in \mathcal{X}} f(x, y)$ . Let's now use this knowledge to design a proper measure of progress towards the saddle point.

We might be tempted to use  $f(x', y') - f(x^*, y^*)$  as a measure of suboptimality of (x', y') with respect to the saddle point  $(x^*, y^*)$ . Unfortunately, this quantity can be negative or equal to zero for an infinite number of points (x', y') that are not saddle points. We might then think to use some notion of distance to the saddle point, like  $\|x'-x^*\|_2^2 + \|y'-y^*\|_2^2$ , but this quantity in general can go to zero at an arbitrarily slow rate. To see why consider the case that f(x, y) = h(x), so that the saddle point problem reduces to minimize a convex function. So, assuming only convexity, the rate of convergence to a minimizer of f can be arbitrarily slow. Hence, we need something different.

Observe that the Theorem 12.3 says one of the problems we should solve is

$$\inf_{\boldsymbol{x}\in\mathcal{X}} h(\boldsymbol{x}),$$

where  $h(x) = \sup_{y \in \mathcal{Y}} f(x, y)$ . In this view, the problem looks like a standard offline convex optimization problem, where the objective function has a particular structure. Moreover, in this view we only focus on the variables x. The standard measure of convergence in this case for a point x', the *suboptimality gap*, can be written as

$$h(\boldsymbol{x}') - \inf_{\boldsymbol{x} \in \mathcal{X}} h(\boldsymbol{x}) = \sup_{\boldsymbol{y} \in \mathcal{Y}} f(\boldsymbol{x}', \boldsymbol{y}) - \inf_{\boldsymbol{x} \in \mathcal{X}} \sup_{\boldsymbol{y} \in \mathcal{Y}} f(\boldsymbol{x}, \boldsymbol{y}) \;.$$

We also have to find the maximizer with respect to y of the function  $\inf_{x \in \mathcal{X}} f(x, y)$ , hence we have

$$\sup_{\boldsymbol{u}\in\mathcal{V}} g(\boldsymbol{y}),$$

where  $g(y) = \inf_{x \in \mathcal{X}} f(x, y)$ . This also implies another measure of convergence in which we focus only on the variable y:

$$\sup_{\boldsymbol{y} \in \mathcal{Y}} g(\boldsymbol{y}) - g(\boldsymbol{y}') = \sup_{\boldsymbol{y} \in \mathcal{Y}} \inf_{\boldsymbol{x} \in \mathcal{X}} f(\boldsymbol{x}, \boldsymbol{y}) - \inf_{\boldsymbol{x} \in \mathcal{X}} f(\boldsymbol{x}, \boldsymbol{y}') .$$

Finally, in case we are interested in studying the quality of a joint solution (x', y'), a natural measure is a sum of the two measures above:

$$\sup_{\boldsymbol{y} \in \mathcal{Y}} f(\boldsymbol{x}', \boldsymbol{y}) - \inf_{\boldsymbol{x} \in \mathcal{X}} \sup_{\boldsymbol{y} \in \mathcal{Y}} f(\boldsymbol{x}, \boldsymbol{y}) + \sup_{\boldsymbol{y} \in \mathcal{Y}} \inf_{\boldsymbol{x} \in \mathcal{X}} f(\boldsymbol{x}, \boldsymbol{y}) - \inf_{\boldsymbol{x} \in \mathcal{X}} f(\boldsymbol{x}, \boldsymbol{y}') = \sup_{\boldsymbol{y} \in \mathcal{Y}} f(\boldsymbol{x}', \boldsymbol{y}) - \inf_{\boldsymbol{x} \in \mathcal{X}} f(\boldsymbol{x}, \boldsymbol{y}'),$$

where we assumed the existence of a saddle point to say that  $\inf_{x \in \mathcal{X}} \sup_{y \in \mathcal{Y}} f(x, y) = \sup_{y \in \mathcal{Y}} \inf_{x \in \mathcal{X}} f(x, y)$  from Theorem 12.3. This measure is called *duality gap*.

**Definition 12.9** (Duality Gap). For a function  $f: \mathcal{X} \times \mathcal{Y} \to \mathbb{R}$ , define the duality gap on  $(x', y') \in \mathcal{X} \times \mathcal{Y}$  as

$$\sup_{\boldsymbol{y} \in \mathcal{Y}} f(\boldsymbol{x}', \boldsymbol{y}) - \inf_{\boldsymbol{x} \in \mathcal{X}} f(\boldsymbol{x}, \boldsymbol{y}')$$

The duality gap is always non-negative even when the saddle point does not exist, since  $\sup_{\boldsymbol{y} \in \mathcal{Y}} f(\boldsymbol{x}', \boldsymbol{y}) \geq \inf_{\boldsymbol{x} \in \mathcal{X}} f(x, y')$ , for all  $\boldsymbol{x}' \in \mathcal{X}$  and  $\boldsymbol{y}' \in \mathcal{Y}$ .

Let's add even more intuition of the duality gap definition, using the one of  $\epsilon$ -saddle point.

**Definition 12.10** ( $\epsilon$ -Saddle-Point). Let  $\epsilon \geq 0$ ,  $\mathcal{X} \subseteq \mathbb{R}^n$ ,  $\mathcal{Y} \subseteq \mathbb{R}^m$ , and  $f : \mathcal{X} \times \mathcal{Y} \to \mathbb{R}$ . A point  $(\boldsymbol{x}^*, \boldsymbol{y}^*) \in \mathcal{X} \times \mathcal{Y}$  is an  $\epsilon$ -saddle point of f in  $\mathcal{X} \times \mathcal{Y}$  if

$$f(x^*, y) - \epsilon \le f(x^*, y^*) \le f(x, y^*) + \epsilon, \quad \forall x \in \mathcal{X}, y \in \mathcal{Y}.$$

This definition is useful because we cannot expect to numerically calculate a saddle point with infinite precision, but we can be find something that satisfies the saddle point definition up to an  $\epsilon$ . Obviously, any saddle point is also an  $\epsilon$ -saddle point.

Now, the notion of  $\epsilon$ -saddle point is equivalent up to a multiplicative constant to the  $\epsilon$  duality gap, as detailed in the next lemma. The proof is left as an exercise (see Exercise 12.1).

**Lemma 12.11.** If  $(x^*, y^*)$  is an  $\epsilon$ -saddle point then its duality gap is upper bounded by  $2\epsilon$ . On the other hand, a duality gap of  $2\epsilon$  and the existence of a saddle point imply that the point is a  $2\epsilon$ -saddle.

The above reasoning tells us that finding the saddle point of the function f is equivalent to solving a maximization problem and a minimization problem. However, as we said above, the saddle point might not exist. So, let's now move to easily checkable sufficient conditions for the existence of a saddle point. For this, we can state the following theorem.

**Theorem 12.12.** Let  $\mathcal{X}$ ,  $\mathcal{Y}$  be compact convex subsets of  $\mathbb{R}^n$  and  $\mathbb{R}^m$  respectively. Let  $f: \mathcal{X} \times \mathcal{Y} \to \mathbb{R}$  a continuous function, convex in its first argument, and concave in its second, and Lipschitz with respect to both. Then, we have that

$$\min_{\boldsymbol{x} \in \mathcal{X}} \max_{\boldsymbol{y} \in \mathcal{Y}} \ f(\boldsymbol{x}, \boldsymbol{y}) = \max_{\boldsymbol{y} \in \mathcal{Y}} \min_{\boldsymbol{x} \in \mathcal{X}} \ f(\boldsymbol{x}, \boldsymbol{y}) \ .$$

This theorem gives us sufficient conditions to have the min-max problem equal to the max-min one. So, for example, thanks to the Weierstrass theorem (Theorem E.8), the assumptions in Theorem 12.12, in light of Theorem 12.3, are sufficient conditions for the existence of a saddle point.

We defer the proof of this theorem for a bit and we now turn ways to solve the saddle point problem in (12.1).

# 12.2 Solving Saddle-Point Problems with OCO

Let's show how to use Online Convex Optimization (OCO) algorithms to solve saddle point problems. We will state a procedure that is a direct generalization of the online-to-batch conversion we saw in Chapter 3.

#### Algorithm 12.1 Solving Saddle-Point Problems with OCO

```
Require: x_1 \in \mathcal{X}, y_1 \in \mathcal{Y}
```

- 1: **for** t = 1, ..., T **do**
- 2:  $\mathcal{X}$ -Learner and  $\mathcal{Y}$ -Learner simultaneously decide their outputs  $x_t \in \mathcal{X}$  and  $y_t \in \mathcal{Y}$
- 3:  $\mathcal{X}$ -Learner receives  $\ell_t(\boldsymbol{x}) = f(\boldsymbol{x}, \boldsymbol{y}_t)$
- 4:  $\mathcal{Y}$ -Learner receives  $h_t(\mathbf{y}) = -f(\mathbf{x}_t, \mathbf{y})$
- 5. end for
- 6: **return**  $\bar{\boldsymbol{x}}_T = \frac{1}{T} \sum_{t=1}^T \boldsymbol{x}_t, \bar{\boldsymbol{y}}_T = \frac{1}{T} \sum_{t=1}^T \boldsymbol{y}_t$

Suppose to use an OCO algorithm fed with losses  $\ell_t(\boldsymbol{x}) = f(\boldsymbol{x}, \boldsymbol{y}_t)$  that produces the iterates  $\boldsymbol{x}_t$  and another OCO algorithm fed with losses  $h_t(\boldsymbol{y}) = -f(\boldsymbol{x}_t, \boldsymbol{y})$  that produces the iterates  $\boldsymbol{y}_t$ . Then, we can state the following Theorem.

**Theorem 12.13.** Let  $f: \mathcal{X} \times \mathcal{Y} \to \mathbb{R}$ . Then, with the notation in Algorithm 12.1, for any  $x \in \mathcal{X}$ , we have

$$\frac{1}{T} \sum_{t=1}^{T} f(\boldsymbol{x}_t, \boldsymbol{y}_t) - \frac{1}{T} \sum_{t=1}^{T} f(\boldsymbol{x}, \boldsymbol{y}_t) = \frac{\operatorname{Regret}_T^{\mathcal{X}}(\boldsymbol{x})}{T},$$

where Regret $_T^{\mathcal{X}}(\boldsymbol{x}) = \sum_{t=1}^T \ell_t(\boldsymbol{x}_t) - \sum_{t=1}^T \ell_t(\boldsymbol{x})$ .

Moreover, for any  $\boldsymbol{y} \in \mathcal{Y}$ , we have

$$\frac{1}{T} \sum_{t=1}^{T} f(\boldsymbol{x}_t, \boldsymbol{y}) - \frac{1}{T} \sum_{t=1}^{T} f(\boldsymbol{x}_t, \boldsymbol{y}_t) = \frac{\operatorname{Regret}_T^{\mathcal{Y}}(\boldsymbol{y})}{T},$$

where  $\operatorname{Regret}_T^{\mathcal{Y}}(\boldsymbol{y}) = \sum_{t=1}^T h_t(\boldsymbol{y}_t) - \sum_{t=1}^T h_t(\boldsymbol{y})$ .

Also, if f is convex in the first argument and concave in the second and  $\operatorname{arg} \max_{\boldsymbol{y} \in \mathcal{Y}} f(\bar{\boldsymbol{x}}_T, \boldsymbol{y})$  and  $\operatorname{arg} \min_{\boldsymbol{x} \in \mathcal{X}} f(\boldsymbol{x}, \bar{\boldsymbol{y}}_T)$ are non-empty, then we have

$$\max_{\boldsymbol{y} \in \mathcal{Y}} f(\bar{\boldsymbol{x}}_T, \boldsymbol{y}) - \min_{\boldsymbol{x} \in \mathcal{X}} f(\boldsymbol{x}, \bar{\boldsymbol{y}}_T) \leq \frac{\operatorname{Regret}_T^{\mathcal{X}}(\boldsymbol{x}_T') + \operatorname{Regret}_T^{\mathcal{Y}}(\boldsymbol{y}_T')}{T},$$

for any  $x'_T \in \arg\min_{x \in \mathcal{X}} f(x, \bar{y}_T)$  and  $y'_T \in \arg\max_{y \in \mathcal{Y}} f(\bar{x}_T, y)$ .

*Proof.* The first two equalities are obtained simply observing that  $\ell_t(x) = f(x, y_t)$  and  $h_t(y) = -f(x_t, y)$ . For the inequality, using Jensen's inequality, we obtain

$$f(\bar{\boldsymbol{x}}_T, \boldsymbol{y}) - f(\boldsymbol{x}, \bar{\boldsymbol{y}}_T) \leq \frac{1}{T} \sum_{t=1}^T f(\boldsymbol{x}_t, \boldsymbol{y}) - \frac{1}{T} \sum_{t=1}^T f(\boldsymbol{x}, \boldsymbol{y}_t) .$$

Summing the first two equalities, using the above inequality, and taking  $m{x} = m{x}_T' \in \arg\min_{m{x} \in \mathcal{X}} f(m{x}, m{\bar{y}}_T)$  and  $y = y_T' \in \arg \max_{y \in \mathcal{Y}} f(\bar{x}_T, y)$ , we get the stated inequality.

From this theorem and Lemma 12.11, we can immediately prove the following corollary.

**Corollary 12.14.** Let  $f: \mathcal{X} \times \mathcal{Y} \to \mathbb{R}$  continuous and assume that  $\mathcal{X}$  and  $\mathcal{Y}$  are compact. Consider Algorithm 12.1 and assume that the two online algorithms guarantee that their maximum regret over competitors in their feasible set is sublinear in T. Then, we have

$$\lim_{T \to \infty} \max_{\boldsymbol{y} \in \mathcal{Y}} f(\bar{\boldsymbol{x}}_T, \boldsymbol{y}) - \min_{\boldsymbol{x} \in \mathcal{X}} f(\boldsymbol{x}, \bar{\boldsymbol{y}}_T) = 0,$$

and  $(\bar{\boldsymbol{x}}_T, \bar{\boldsymbol{y}}_T)$  converge to a saddle point.

**Example 12.15.** Consider the saddle point problem

$$\min_{|x| \le 2} \max_{|y| \le 2} (x - 1)(y - 1) .$$

The saddle point of this problem is (x,y)=(1,1). We can find it using, for example, Projected Online Gradient Descent with stepsizes  $\eta_t = \frac{1}{\sqrt{t}}$ . So, setting  $x_1 = y_1 = 0$ , we have the iterations

$$x_{t+1} = \max\left(\min\left(x_t - \frac{1}{\sqrt{t}}(y_t - 1), 2\right), -2\right)$$
  
 $y_{t+1} = \max\left(\min\left(y_t + \frac{1}{\sqrt{t}}(x_t - 1), 2\right), -2\right).$ 

According to Theorem 12.13, the duality gap in  $(\frac{1}{T}\sum_{t=1}^{T}x_t, \frac{1}{T}\sum_{t=1}^{T}y_t)$  converges to 0.

Surprisingly, we can even prove a (simpler version of the) minimax theorem from the above result! In particular, we will use the additional assumption that there exist OCO algorithms that minimize  $\ell_t$  and  $h_t$  have sublinear regret.

Proof of Theorem 12.12 with OCO assumption. From Lemma 12.2, we have one inequality. Hence, we now have to prove the other inequality.

We will use a constructive proof. Let's use Algorithm 12.1 and Theorem 12.13. For the first player, for any  $x \in \mathcal{X}$ we have

$$\frac{1}{T}\sum_{t=1}^T f(\boldsymbol{x}_t, \boldsymbol{y}_t) = \frac{1}{T}\sum_{t=1}^T f(\boldsymbol{x}, \boldsymbol{y}_t) + \frac{\operatorname{Regret}_T^{\mathcal{X}}(\boldsymbol{x})}{T} \leq f\left(\boldsymbol{x}, \frac{1}{T}\sum_{t=1}^T \boldsymbol{y}_t\right) + \frac{\operatorname{Regret}_T^{\mathcal{X}}(\boldsymbol{x})}{T} \; .$$

Observe that

$$\min_{\boldsymbol{x} \in \mathcal{X}} f\left(\boldsymbol{x}, \frac{1}{T} \sum_{t=1}^{T} \boldsymbol{y}_{t}\right) \leq \max_{\boldsymbol{y} \in \mathcal{Y}} \min_{\boldsymbol{x} \in \mathcal{X}} f(\boldsymbol{x}, \boldsymbol{y}) \; .$$

Hence, using an OCO algorithm that has o(T) regret for each  $x \in \mathcal{X}$ , we have

$$\frac{1}{T} \sum_{t=1}^{T} f(\boldsymbol{x}_t, \boldsymbol{y}_t) \leq \max_{\boldsymbol{y} \in \mathcal{Y}} \min_{\boldsymbol{x} \in \mathcal{X}} f(\boldsymbol{x}, \boldsymbol{y}) + o(1) .$$

In the same way, we have

$$-\frac{1}{T} \sum_{t=1}^{T} f(\boldsymbol{x}_t, \boldsymbol{y}_t) \le -\min_{\boldsymbol{x} \in \mathcal{X}} \max_{\boldsymbol{y} \in \mathcal{Y}} f(\boldsymbol{x}, \boldsymbol{y}) + o(1) .$$

Summing the two inequalities, taking  $T \to \infty$ , and using the sublinear regret assumption, we have

$$\min_{\boldsymbol{x} \in \mathcal{X}} \max_{\boldsymbol{y} \in \mathcal{Y}} f(\boldsymbol{x}, \boldsymbol{y}) \leq \max_{\boldsymbol{y} \in \mathcal{Y}} \min_{\boldsymbol{x} \in \mathcal{X}} f(\boldsymbol{x}, \boldsymbol{y}) \;.$$

Together with Lemma 12.2, this implies the stated equality.

#### 12.2.1 **Variations with Best Response and Alternation**

In some cases, it is easy to compute the max with respect to  $y \in \mathcal{Y}$  of  $f(x_t, y)$  for a given  $x_t$ . For example, this is trivial for bilinear games over the probability simplex that we will see in Section 12.3. In these cases, we can remove the second learner and just use its best response in each round. Note that in this way we are making one of the two players "stronger" through the knowledge of its loss of the next round. However, this is perfectly fine: The proof in Theorem 12.13 is still perfectly valid.

#### **Algorithm 12.2** Saddle-Point Optimization with OCO and *Y*-Best-Response

Require:  $x_1 \in \mathcal{X}$ 

- 1: **for** t = 1, ..., T **do**
- Set  $m{y}_t \in \operatorname{argmax}_{m{y} \in \mathcal{Y}} \ f(m{x}_t, m{y})$   $\mathcal{X}$ -Learner receives  $\ell_t(m{x}) = f(m{x}, m{y}_t)$  and produces  $m{x}_{t+1} \in \mathcal{X}$
- 5: **return**  $\bar{\boldsymbol{x}}_T = \frac{1}{T} \sum_{t=1}^T \boldsymbol{x}_t, \bar{\boldsymbol{y}}_T = \frac{1}{T} \sum_{t=1}^T \boldsymbol{y}_t$

In this case, the *Y*-player has an easy life: it knows the loss before making the prediction, hence it can just output the minimizer of the loss in  $\mathcal{Y}$ . Hence, we also have that the regret of the  $\mathcal{Y}$ -player will be non-positive and it will not show up in Theorem 12.13. Putting all together, we can state the following corollary.

**Corollary 12.16.** Let  $f: \mathcal{X} \times \mathcal{Y} \to \mathbb{R}$  be convex in the first argument, and concave in the second. With the notation in Algorithm 12.2, assume that  $\mathcal{X}$  is compact, the argmax of the  $\mathcal{Y}$ -player is never empty, and  $\arg\min_{\boldsymbol{x}\in\mathcal{X}} f(\boldsymbol{x},\bar{\boldsymbol{y}}_T)$ is not-empty. Then, we have

$$\sup_{\boldsymbol{y} \in \mathcal{Y}} f(\bar{\boldsymbol{x}}_T, \boldsymbol{y}) - \min_{\boldsymbol{x} \in \mathcal{X}} f(\boldsymbol{x}, \bar{\boldsymbol{y}}_T) \le \frac{\operatorname{Regret}_T^{\mathcal{X}}(\boldsymbol{x}_T')}{T},$$

for any 
$$x_T' \in \arg\min_{x \in \mathcal{X}} f(x, \bar{y}_T)$$
 and where  $\operatorname{Regret}_T^{\mathcal{X}}(x) = \sum_{t=1}^T \ell_t(x_t) - \sum_{t=1}^T \ell_t(x)$ .

This alternative seems interesting from a theoretical point of view because it allows to avoid the complexity of learning in the  $\mathcal{Y}$  space, for example removing the dependency on its dimension.

**Remark 12.17.** The best-response algorithm requires a stronger access to the function f because we need to solve exactly an optimization problem. Hence, for example, we cannot just have access to gradients of f to use it.

Of course, an analogous result can be stated using best-response for the  $\mathcal{X}$ -player and an OCO algorithm for the  $\mathcal{Y}$ -player, as in Algorithm 12.3.

# **Algorithm 12.3** Saddle-Point Optimization with OCO and $\mathcal{X}$ -Best-Response

```
Require: \mathbf{y}_1 \in \mathcal{Y}

1: \mathbf{for} \ t = 1, \dots, T \ \mathbf{do}

2: \mathbf{Set} \ \mathbf{x}_t = \mathbf{argmin}_{\mathbf{x} \in \mathcal{X}} \ f(\mathbf{x}, \mathbf{y}_t)

3: \mathcal{Y}-Learner receives h_t(\mathbf{y}) = -f(\mathbf{x}_t, \mathbf{y}) and produces \mathbf{y}_{t+1} \in \mathcal{Y}

4: \mathbf{end} \ \mathbf{for}

5: \mathbf{return} \ \bar{\mathbf{x}}_T = \frac{1}{T} \sum_{t=1}^T \mathbf{x}_t, \ \bar{\mathbf{y}}_T = \frac{1}{T} \sum_{t=1}^T \mathbf{y}_t
```

There is a third variant, very used in empirical implementations, especially of Counterfactual Regret Minimization (CFR) [Zinkevich et al., 2007]. It is called *alternation* and it breaks the simultaneous reveal of the actions of the two players. Instead, we use the updated prediction of the first player to construct the loss of the second player. Empirically, this variant seems to greatly speed-up the convergence of the duality gap.

# Algorithm 12.4 Saddle-Point Optimization with OCO and Alternation

```
Require: \mathbf{y}_1 \in \mathcal{Y}

1: for t = 1, \dots, T do

2: \mathcal{X}-Learner receives \ell_t(\mathbf{x}) = f(\mathbf{x}, \mathbf{y}_t) and produces \mathbf{x}_{t+1} \in \mathcal{X}

3: \mathcal{Y}-Learner receives h_t(\mathbf{y}) = -f(\mathbf{x}_{t+1}, \mathbf{y}) and produces \mathbf{y}_{t+1} \in \mathcal{Y}

4: end for

5: return \bar{\mathbf{x}}_T = \frac{1}{T} \sum_{t=1}^T \mathbf{x}_{t+1}, \bar{\mathbf{y}}_T = \frac{1}{T} \sum_{t=1}^T \mathbf{y}_t
```

For this version, Theorem 12.13 does not hold anymore because the terms  $f(x_t, y_t)$  and  $f(x_{t+1}, y_t)$  are now different, however we can prove a similar guarantee.

**Theorem 12.18.** Let  $f: \mathcal{X} \times \mathcal{Y} \to \mathbb{R}$  convex in the first argument and concave in the second. With the notation in Algorithm 12.4, assume that  $\arg\min_{\boldsymbol{x}\in\mathcal{X}} f(\boldsymbol{x},\bar{\boldsymbol{y}}_T)$  and  $\arg\max_{\boldsymbol{y}\in\mathcal{Y}} f(\bar{\boldsymbol{x}}_T,\boldsymbol{y})$  are non-empty. Then, for any  $\boldsymbol{x}_T' \in \arg\max_{\boldsymbol{x}\in\mathcal{Y}} f(\bar{\boldsymbol{x}}_T,\boldsymbol{y})$ , we have

$$\max_{\boldsymbol{y} \in \mathcal{Y}} f(\bar{\boldsymbol{x}}_T, \boldsymbol{y}) - \min_{\boldsymbol{x} \in \mathcal{X}} f(\boldsymbol{x}, \bar{\boldsymbol{y}}_T) \leq \frac{\operatorname{Regret}_T^{\mathcal{X}}(\boldsymbol{x}_T') + \operatorname{Regret}_T^{\mathcal{Y}}(\boldsymbol{y}_T') + \sum_{t=1}^T (f(\boldsymbol{x}_{t+1}, \boldsymbol{y}_t) - f(\boldsymbol{x}_t, \boldsymbol{y}_t))}{T},$$

where 
$$\operatorname{Regret}_{T}^{\mathcal{Y}}(\boldsymbol{y}) = \sum_{t=1}^{T} h_{t}(\boldsymbol{y}_{t}) - \sum_{t=1}^{T} h_{t}(\boldsymbol{y})$$
,  $\operatorname{Regret}_{T}^{\mathcal{X}}(\boldsymbol{x}) = \sum_{t=1}^{T} \ell_{t}(\boldsymbol{x}_{t}) - \sum_{t=1}^{T} \ell_{t}(\boldsymbol{x})$ .

*Proof.* Note that  $\ell_t(x) = f(x, y_t)$ , and  $h_t(y) = -f(x_{t+1}, y)$ . By Jensen's inequality, we have

$$\begin{split} T(f(\bar{\boldsymbol{x}}_T, \boldsymbol{y}) - f(\boldsymbol{x}, \bar{\boldsymbol{y}}_T)) &\leq \sum_{t=1}^T f(\boldsymbol{x}_{t+1}, \boldsymbol{y}) - \sum_{t=1}^T f(\boldsymbol{x}, \boldsymbol{y}_t) \\ &= \sum_{t=1}^T f(\boldsymbol{x}_{t+1}, \boldsymbol{y}) - \sum_{t=1}^T f(\boldsymbol{x}_{t+1}, \boldsymbol{y}_t) + \sum_{t=1}^T f(\boldsymbol{x}_t, \boldsymbol{y}_t) - \sum_{t=1}^T f(\boldsymbol{x}, \boldsymbol{y}_t) \\ &+ \sum_{t=1}^T f(\boldsymbol{x}_{t+1}, \boldsymbol{y}_t) - \sum_{t=1}^T f(\boldsymbol{x}_t, \boldsymbol{y}_t) \\ &= \sum_{t=1}^T (h_t(\boldsymbol{y}_t) - h_t(\boldsymbol{y})) + \sum_{t=1}^T (\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{x})) + \sum_{t=1}^T (f(\boldsymbol{x}_{t+1}, \boldsymbol{y}_t) - f(\boldsymbol{x}_t, \boldsymbol{y}_t)) \;. \end{split}$$

Taking  $x = x_T' \in \arg\min_{x \in \mathcal{X}} f(x, \bar{y}_T)$  and  $y = y_T' \in \arg\max_{y \in \mathcal{Y}} f(\bar{x}_T, y)$ , we get the stated result.

**Remark 12.19.** In some cases, it is possible to show that the additional term in Theorem 12.18 is negative, showing a (marginal) improvement to the convergence rate. For example, using OMD for the  $\mathcal{X}$ -player and assuming that the losses it receives are linear, we have that  $f(\mathbf{x}_t, \mathbf{y}_t) = \ell_t(\mathbf{x}_t) \ge \ell_t(\mathbf{x}_{t+1}) = f(\mathbf{x}_{t+1}, \mathbf{y}_t)$ .

Next, we will show how to connect saddle point problems with Game Theory.

# 12.3 Game-Theory interpretation of Saddle-Point Problems

An instantiation of a saddle point problems also has an interpretation in Game Theory as a *Two-player Zero-Sum Game*. Note that Game Theory is a vast field and two-person zero-sum games are only a very small subset of the problems in this domain and what I describe here is an even smaller subset of this subset of problems.

Game theory studies what happens when self-interested agents interact. By self-interested, we mean that each agent has an ideal state of things he wants to reach, that can include a description of what should happen to other agents as well, and he works towards this goal. In two-person games the players act simultaneously and then they receive their losses. In particular, the  $\mathcal{X}$ -player chooses the play x and the y-player chooses the play y, the y-player suffers the loss y-player the loss y-player the loss y-player the loss only one play for each player. Note that the standard game-theoretic terminology uses payoffs instead of losses, but we will keep using losses for coherence with the online convex optimization notation we use in this book.

We consider the so-called two-person normal-form games, that is when the first player has n possible actions and the second player m. A player can use a pure strategy, that is a single fixed action, or randomize over a set of actions according to some probability distribution, a so-called mixed strategy. In this case, we consider  $\mathcal{X} = \Delta^{n-1}$  and  $\mathcal{Y} = \Delta^{m-1}$  and they are known as the action spaces for the two players. In this setting, for a pair of pure strategies  $(e_i, e_j)$ , the first player receives the loss  $f(e_i, e_j)$  and the second player  $-f(e_i, e_j)$ , where  $e_i$  is the vector with all zeros but a '1' in position i. The goal of each player is to minimize the received loss. Given the discrete nature of this game, the function f(x, y) is the bilinear function  $x^T M y$ , where M is a matrix with n rows and m columns. Hence, for a pair of mixed strategy (x, y), the expected loss of the first player is  $x^T M y$  and the one of the second player is  $-x^T M y$ .

A fundamental concept in game theory is the one of *Nash Equilibrium*. We have a Nash equilibrium if all players are playing their best strategy to the other players' strategies. That is, none of the players has incentive to change their strategy if the other player does not change it. For the zero-sum two-person game, this can be formalized saying that  $(x^*, y^*)$  is a Nash equilibrium if

$$(\boldsymbol{x}^{\star})^{\top}\boldsymbol{M}\boldsymbol{y} \leq (\boldsymbol{x}^{\star})^{\top}\boldsymbol{M}\boldsymbol{y}^{\star} \leq \boldsymbol{x}^{\top}\boldsymbol{M}\boldsymbol{y}^{\star}, \quad \forall \boldsymbol{x} \in \Delta^{n-1}, \boldsymbol{y} \in \Delta^{m-1} \ .$$

This is *exactly* the definition of saddle point for the function  $f(x, y) = x^{\top} M y$  that we gave in the previous section. Given that  $f(x, y) = x^{\top} M y$  is continuous, convex in the first argument and concave in the second one, the sets  $\mathcal{X} = \Delta^{n-1}$  and  $\mathcal{Y} = \Delta^{m-1}$  are convex and compacts, we can deduce from Theorem 12.12 and Theorem 12.3 that

a saddle point always exists. Hence, there is always at least one (possibly mixed) Nash equilibrium in two-person zero-sum games. The common value of the minimax and maxmin problem is called *value of the game* and we will denote it by  $v^*$ .

For zero-sum two-person game the Nash equilibrium has an immediate interpretation: From the definition above, if the first player uses the strategy  $x^*$  then his loss is less then the value of the game  $v^*$ , regardless of the strategy of the second player. Analogously, if the second player uses the strategy  $y^*$  then his loss is less then  $-v^*$ , regardless of the strategy of the first player. Both players achieve the value of the game if they both play the Nash strategy. Moreover, even if one of the players would announce his strategy in advance to the other player, he would not increase his loss in expectation.

**Example 12.20** (Cake cutting). Suppose to have a game between two people: The first player cuts the cake in two and the second one chooses a piece; the first player receives the piece that was not chosen. We can formalize it with the following matrix:

	larger piece	smaller piece
cut evenly	0	0
cut unevenly	10	-10

When the first player plays action i and the second player action j, the first player receives the loss  $M_{i,j}$  and the second player receives  $-M_{i,j}$ . The losses represent how much less in percentage compared to half of the cake the first player is receiving. The second player receives the negative of the same number. It should be easy to convince oneself that the strategy pair is (cut evenly, larger piece) is an equilibrium with value of the game of 0. However, perhaps counter intuitively, this is not the only optimal strategy. In fact, for  $0.5 \le a \le 1$ , one can verify numerically that any pair  $\mathbf{x}^* = [1,0]^\top$ ,  $\mathbf{y}^* = [a,1-a]$  is optimal, where the first player uses a pure strategy and the second player a mixed one.

**Example 12.21** (Rock-paper-scissors). Let's consider the game of Rock-paper-scissors. We describe it with the following matrix:

	Rock	Paper	Scissors
Rock	0	1	-1
Paper	-1	0	1
Scissors	1	-1	0

It should be immediate to realize that there are no pure Nash equilibria for this game. However, there is a mixed Nash equilibrium when each player randomize the action with a uniform probability distribution over the three actions and value of the game equals to 0.

**Example 12.22** (Matching Pennies). In this game, both players show a face of a penny. If the two faces are the same, the first player wins both, otherwise the second player wins both. The associated matrix M is

It is easy to see that the Nash equilibrium is when both players randomize the face to show with equal probability. In this simple case, we can visualize the saddle point associated to this problem in Figure 12.2

Unless the game is very small, we find Nash equilibria using numerical procedures that typically give us only approximate solutions. Hence, as for  $\epsilon$ -saddle points, for  $\epsilon \geq 0$  we also define an  $\epsilon$ -Nash equilibrium for a zero-sum two-person game when  $\boldsymbol{x}^{\star}$  and  $\boldsymbol{y}^{\star}$  satisfy

$$({m x}^\star)^ op {m M}{m y} - \epsilon \le ({m x}^\star)^ op {m M}{m y}^\star \le {m x}^ op {m M}{m y}^\star + \epsilon, \quad orall {m x} \in \Delta^{n-1}, {m y} \in \Delta^{m-1} \ .$$

Obviously, any Nash equilibrium is also an  $\epsilon$ -Nash equilibrium.

From what we said in the previous section, it should be immediate to see how to numerically calculate the Nash equilibrium of a two-person zero-sum game. In fact, we know that we can use online convex optimization algorithms to find  $\epsilon$ -saddle points, so we can do the same for  $\epsilon$ -Nash equilibrium of two-person zero-sum games. Assuming that the average regret of both players is  $\epsilon_T$ , Theorem 12.13 says that  $\left(\frac{1}{T}\sum_{t=1}^T \boldsymbol{x}_t, \frac{1}{T}\sum_{t=1}^T \boldsymbol{y}_t\right)$  is a  $2\epsilon_T$ - Nash equilibrium.

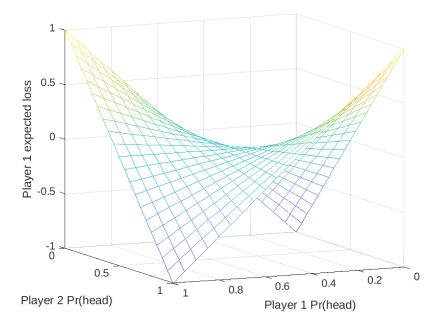

Figure 12.2: The saddle point in the Matching Pennies game.

# 12.4 Boosting as a Two-Person Game

We will now show that the Boosting problem can also be seen as the solution of a zero-sum two-person game.

Let  $S = \{z_j, y_j\}_{j=1}^m$  a training set of m couples features/labels, where  $z_i \in \mathbb{R}^d$  and  $y_i = \{-1, 1\}$ . Let  $\mathcal{H} = \{h_i\}_{i=1}^n$  a set of n functions  $h_i : \mathbb{R}^d \to \{-1, 1\}$ . The aim of boosting is to find a combination of the functions in  $\mathcal{H}$  that has arbitrarily low misclassification error on S. Of course, this is not always possible. However, we will make a (strong) assumption: We assume that it is always possible to find a function  $h_i \in \mathcal{H}$  such that its misclassification error over S weighted with any probability distribution is better than chance by a constant  $\gamma > 0$ . We now show that this assumption guarantees that the boosting problem is solvable!

First, we construct a matrix of the misclassifications for each function:  $M \in \mathbb{R}^{n \times m}$  where

$$M_{i,j} = \begin{cases} 1, & \text{if } h_i(\boldsymbol{z}_j) \neq y_j \\ 0, & \text{otherwise.} \end{cases}$$

Setting  $\mathcal{X} = \Delta^{n-1}$  and  $\mathcal{Y} = \Delta^{m-1}$ , we write the saddle point problem/two-person zero-sum game

$$\min_{oldsymbol{p} \in \Delta^{n-1}} \max_{oldsymbol{q} \in \Delta^{m-1}} \ oldsymbol{p}^{ op} oldsymbol{M} oldsymbol{q}$$
 .

Given the definition of the matrix M, this is equivalent to

$$\min_{\boldsymbol{p} \in \Delta^{n-1}} \max_{\boldsymbol{q} \in \Delta^{m-1}} \sum_{i=1}^{n} \sum_{j=1}^{m} p_i q_j \mathbf{1} [h_i(\boldsymbol{z}_j) \neq y_j] .$$

Let's now formalize the assumption on the functions: We assume the existence of a *weak learning oracle* that, for any  $q \in \Delta^{m-1}$ , returns  $i^*$  such that

$$\boldsymbol{e}_{i^{\star}}^{\top} \boldsymbol{M} \boldsymbol{q} = \sum_{j=1}^{m} q_{j} \mathbf{1} [h_{i^{\star}}(\boldsymbol{z}_{j}) \neq y_{j}] \leq \frac{1}{2} - \gamma, \tag{12.4}$$

where  $\gamma > 0$ . In words,  $i^*$  is the index of the function in  $\mathcal{H}$  that gives a q-weighted error better than chance. Moreover, given that

$$\min_{\boldsymbol{p} \in \Delta^{n-1}} \boldsymbol{p}^\top \boldsymbol{M} \boldsymbol{q} \leq \boldsymbol{e}_{i^\star}^\top \boldsymbol{M} \boldsymbol{q} \leq \frac{1}{2} - \gamma$$

and

$$v^{\star} = \max_{\boldsymbol{q} \in \Delta^{m-1}} \min_{\boldsymbol{p} \in \Delta^{n-1}} \boldsymbol{p}^{\top} \boldsymbol{M} \boldsymbol{q},$$

we have that the value of the game satisfies  $v^\star \leq \frac{1}{2} - \gamma < \frac{1}{2}$ . Using the inequality on the value of the game and the fact that the Nash equilibrium exists, we obtain that there exists  $p^\star \in \Delta^{n-1}$  such that

$$\sum_{i=1}^{n} p_i^{\star} \mathbf{1}[h_i(\boldsymbol{z}_j) \neq y_j] = (\boldsymbol{p}^{\star})^{\top} \boldsymbol{M} \boldsymbol{e}_j \leq v^{\star} \leq \frac{1}{2} - \gamma < \frac{1}{2}, \ \forall j = 1, \dots, m.$$
 (12.5)

In words, this means that every sample  $z_i$  is misclassified by less than half of the functions  $h_i$  when weighted by  $p^*$ . Hence, we can correctly classify all the samples using a weighted majority vote rule where the weights over the function  $h_i$  are  $p^*$ . This means that we can learn a perfect classifier rule using weak learners, through the solution of a minimax game. So, our job is to find a way to calculate this optimal distribution  $p^*$  on the functions.

Given what we have said till now, a natural strategy is to use online convex optimization algorithms. In particular, we can use Algorithm 12.3, where in each round the  $\mathcal{X}$ -player is the weak learning oracle, that knows the play  $q_t$ by the Y-Learner and produces a best response or an approximate best response. In particular, from the assumption on the weak-learnability oracle in (12.4), the  $\mathcal{X}$ -learner can always find a classifier with small enough  $q_t$ -weighted training error. Instead, the  $\mathcal{Y}$ -player is an OCO algorithm. Specialized to our setting we have the following algorithm. In words, the  $\mathcal{X}$ -player looks for the function that has small enough weighted misclassification loss, where the weights are constructed by the  $\mathcal{Y}$ -player.

#### Algorithm 12.5 Boosting through OCO

- 1:  $q_{1,j} = 1/m, j = 1, \dots, m$
- 2: **for** t = 1, ..., T **do**
- $\mathcal{X}$ -Learner has two possible strategies:
  - i) (Approximate Best Response) Set  $i_t$  such that  $e_{i_t}^{\top} M q_t = \sum_{j=1}^m q_{t,j} \mathbf{1} [h_{i_t}(\boldsymbol{z}_j) \neq y_j] \leq 1/2 \gamma$  ii) (Best Response) Set  $i_t = \operatorname{argmin}_{i=1,\dots,n} e_i^{\top} M q_t = \operatorname{argmin}_{i=1,\dots,n} \sum_{j=1}^m q_{t,j} \mathbf{1} [h_i(\boldsymbol{z}_j) \neq y_j]$   $\mathcal{Y}$ -Learner receives  $\ell_t(\boldsymbol{q}) = -e_{i_t}^{\top} M q = -\sum_{j=1}^m q_j \mathbf{1} [h_{i_t}(\boldsymbol{z}_j) \neq y_j]$  and produces  $q_{t+1} \in \Delta^{m-1}$

- 6: **return**  $\bar{h}_T(z) = \frac{1}{T} \sum_{t=1}^{T} h_{i_t}(z)$

Let's show a guarantee on the misclassification error of this algorithm. From the second equality of Theorem 12.13, for any  $q \in \Delta^{m-1}$ , we have

$$\frac{1}{T} \sum_{t=1}^{T} \boldsymbol{e}_{i_t}^{\top} \boldsymbol{M} \boldsymbol{q} = \frac{1}{T} \sum_{t=1}^{T} \boldsymbol{e}_{i_t}^{\top} \boldsymbol{M} \boldsymbol{q}_t + \frac{\operatorname{Regret}_T^{\mathcal{Y}}(\boldsymbol{q})}{T} .$$

From both strategies of the  $\mathcal{X}$ -player, we have  $\frac{1}{T}\sum_{t=1}^{T} e_{i_t}^{\top} M q_t \leq \frac{1}{2} - \gamma$ . Moreover, choosing  $q = e_j$  we have  $\frac{1}{T}\sum_{t=1}^T e_{i_t}^{\mathsf{T}} Mq = \frac{1}{T}\sum_{i=1}^T \mathbf{1}[h_{i_t}(\boldsymbol{z}_j) \neq y_j]$ . Putting all together, we have

$$\frac{1}{T} \sum_{i=1}^{T} \mathbf{1}[h_{i_t}(\boldsymbol{z}_j) \neq y_j] \leq \frac{1}{2} - \gamma + \frac{\operatorname{Regret}_T^{\mathcal{Y}}(\boldsymbol{e}_j)}{T}, \ \forall j = 1, \dots, m.$$

 $\text{If } \frac{\text{Regret}_{\mathcal{T}}^{\mathcal{Y}}(\boldsymbol{e}_j)}{r} < \gamma \text{, less than half of the functions selected by the boosting procedure will make a mistake on } (\boldsymbol{z}_j, y_j).$ Using as predictor the majority rule of the selected functions, we will have 0 mistakes on the training samples.

Observe that in this scheme we construct  $p_i^*$  by approximating it with the frequency with which  $i_t$  is equal to i.

**Remark 12.23.** The use of a best response or approximate best-response for the  $\mathcal{X}$ -player avoids the presence of its regret in the guarantee. In turn, this makes the number of rounds to reach training error 0 to be independent of the number of functions in  $\mathcal{H}$ .

Let's now instantiate this framework with a specific OCO algorithm. For example, using EG as algorithm for the  $\mathcal{Y}$ -player, we have that  $\operatorname{Regret}_T^{\mathcal{Y}}(e_j) = \mathcal{O}(\sqrt{T \ln n})$  as  $T \to \infty$  for any  $j = 1, \ldots, m$ , that implies that after  $T = \mathcal{O}(\frac{\ln n}{\gamma^2})$  rounds the error on the training samples of the classifier that uses the sign of  $\bar{h}_T$  is exactly 0. This is exactly the same guarantee achieved by AdaBoost [Freund and Schapire, 1995, 1997].

**Boosting and Margins** What happens if we keep boosting after the training error reaches 0? It turns out we maximize the *margin*, defined as  $y_j \frac{1}{T} \sum_{t=1}^T h_{i_t}(\boldsymbol{z}_j)$ . In fact, given that  $\mathbf{1}[h_{i_t}(\boldsymbol{z}_j) \neq y_j] = \frac{1-y_j h_{i_t}(\boldsymbol{z}_j)}{2}$ , we have for any  $j=1,\ldots,m$ 

$$2\gamma - \frac{2\operatorname{Regret}_T^{\mathcal{Y}}(\boldsymbol{e}_j)}{T} \leq y_j \frac{1}{T} \sum_{i=1}^T h_{i_t}(\boldsymbol{z}_j) = y_j \bar{h}_T(\boldsymbol{z}_j) .$$

Hence, when the number of rounds goes to infinity the minimum margin on the training samples reaches  $2\gamma$ . This property of boosting of maximizing the margin has been used as an explanation of the fact that in boosting additional rounds after the training error reaches 0 often keep improving the test error on test samples coming i.i.d. from the same distribution that generated the training samples.

The above reduction does not tell us how the training error precisely behaves. However, we can get this information changing the learning with expert algorithm. Indeed, we have seen in Chapter 10 that there are learning with experts algorithms provably better than EG. We can use a learning with experts algorithm that guarantees a regret  $\mathcal{O}(\sqrt{T\cdot \mathrm{KL}(q;\pi)})$  as  $T\to\infty$  for a given prior  $\pi$ , where  $\pi$  is the uniform prior. This kind of algorithms allow us to upper bound the fraction of mistakes after any T iterations. Denote by k the number of misclassified samples after T iterations of boosting and set  $q_k$  as the vector whose coordinates are equal to 1/k if  $\mathrm{sign}(\bar{h}_T(z))$  misclassifies it. Hence, we have

$$2\gamma - \frac{2\operatorname{Regret}_{T}^{\mathcal{Y}}(\boldsymbol{q}_{k})}{T} \le \frac{1}{k} \sum_{j=1}^{k} y_{j} \bar{h}_{T}(\boldsymbol{z}_{j}) \le 0.$$
(12.6)

Using the expression of the regret, we have that the fraction of misclassification errors  $\frac{k}{m}$  is bounded by  $\mathcal{O}(\exp(-\gamma^2 T))$  as  $T \to \infty$ . That is, the fraction of misclassification error goes to zero exponential fast in the number of boosting rounds. Again, a similar guarantee was proved for AdaBoost, but here we quickly derived it using a reduction from boosting to learning with experts, passing through two-person games.

# 12.5 Faster Rates Through Optimism

We saw that it is possible to solve convex/concave saddle point optimization problems using two online convex optimization algorithms playing against each other. We obtained a rate of convergence for the duality gap of  $\mathcal{O}(1/\sqrt{T})$ . Now, we show that if the function is smooth we can achieve a faster rate using optimistic algorithms.

Assume that  $f: \mathcal{X} \times \mathcal{Y} \to \mathbb{R}$  is smooth in an open interval containing its domain, in the sense that for any  $x, x' \in \mathcal{X}$  and  $y, y' \in \mathcal{Y}$ , we have

$$\|\nabla_{\boldsymbol{x}} f(\boldsymbol{x}, \boldsymbol{y}) - \nabla_{\boldsymbol{x}} f(\boldsymbol{x}', \boldsymbol{y})\|_{\mathcal{X}, \star} \le L_{\mathcal{X}\mathcal{X}} \|\boldsymbol{x} - \boldsymbol{x}'\|_{\mathcal{X}}, \tag{12.7}$$

$$\|\nabla_{\boldsymbol{x}} f(\boldsymbol{x}, \boldsymbol{y}) - \nabla_{\boldsymbol{x}} f(\boldsymbol{x}, \boldsymbol{y}')\|_{\mathcal{X}, \star} \le L_{\mathcal{X}\mathcal{Y}} \|\boldsymbol{y} - \boldsymbol{y}'\|_{\mathcal{Y}}, \tag{12.8}$$

$$\|\nabla_{\boldsymbol{y}} f(\boldsymbol{x}, \boldsymbol{y}) - \nabla_{\boldsymbol{y}} f(\boldsymbol{x}', \boldsymbol{y})\|_{\mathcal{Y}, \star} \le L_{\mathcal{X}\mathcal{Y}} \|\boldsymbol{x} - \boldsymbol{x}'\|_{\mathcal{X}}, \tag{12.9}$$

$$\|\nabla_{\boldsymbol{y}} f(\boldsymbol{x}, \boldsymbol{y}) - \nabla_{\boldsymbol{y}} f(\boldsymbol{x}, \boldsymbol{y}')\|_{\mathcal{V}, \star} \le L_{\mathcal{V}\mathcal{V}} \|\boldsymbol{y} - \boldsymbol{y}'\|_{\mathcal{V}}, \tag{12.10}$$

where  $\nabla_x$  and  $\nabla_y$  denote the gradients with respect to the first and second variable respectively, and we have denoted by  $\|\cdot\|_{\mathcal{X}}$  and  $\|\cdot\|_{\mathcal{Y}}$  the norms in  $\mathcal{X}$  and  $\mathcal{Y}$  respectively, while the norms with the  $\star$  are their duals.

**Remark 12.24.** At this point, one might be tempted to consider the maximum between the three quantities "to simplify the math", but the units are different and it does not make any sense to take the maximum between quantities with different units.

Let's use again two online algorithms to solve the saddle point problem  $\min_{x \in \mathcal{X}} \max_{y \in \mathcal{Y}} f(x, y)$ . However, instead of using two standard no-regret algorithms, we will use two *optimistic ones*. Optimistic online algorithms use a hint on the next subgradient. We will use the same strategy and proof of the algorithm in Section 7.12.2, that is we will use the previous observed gradient as a prediction for the next one.

For example, use two Optimistic FTRL algorithms with fixed strongly convex regularizers and hint at time t constructed using the previous observed gradient:  $\tilde{\ell}_t(x) = \langle g_{t-1}, x \rangle$  where we set  $g_0 = 0$ . We now show that these hints allow to cancel out terms when we consider the sum of the regrets and obtain a faster rate of  $\mathcal{O}(1/T)$  rather than just  $\mathcal{O}(1/\sqrt{T})$ .

### Algorithm 12.6 Solving Saddle-Point Problems with Optimistic FTRL

```
Require: \lambda_{\mathcal{X}} > 0, \lambda_{\mathcal{Y}} > 0

1: g_{\mathcal{X},0} = \mathbf{0}, g_{\mathcal{Y},0} = \mathbf{0}

2: for t = 1, \dots, T do

3: \mathbf{x}_t = \operatorname{argmin}_{\mathbf{x} \in \mathcal{X}} \ \psi_{\mathcal{X}}(\mathbf{x}) + \langle g_{\mathcal{X},t-1}, \mathbf{x} \rangle + \sum_{i=1}^{t-1} \langle g_{\mathcal{X},i}, \mathbf{x} \rangle

4: \mathbf{y}_t = \operatorname{argmin}_{\mathbf{y} \in \mathcal{Y}} \ \psi_{\mathcal{Y}}(\mathbf{y}) + \langle g_{\mathcal{Y},t-1}, \mathbf{y} \rangle + \sum_{i=1}^{t-1} \langle g_{\mathcal{Y},i}, \mathbf{y} \rangle

5: Set g_{\mathcal{X},t} = \nabla_{\mathbf{x}} f(\mathbf{x}_t, \mathbf{y}_t)

6: Set g_{\mathcal{Y},t} = -\nabla_{\mathbf{y}} f(\mathbf{x}_t, \mathbf{y}_t)

7: end for

8: return \bar{\mathbf{x}}_T = \frac{1}{T} \sum_{t=1}^T \mathbf{x}_t, \bar{\mathbf{y}}_T = \frac{1}{T} \sum_{t=1}^T \mathbf{y}_t
```

From the regret of Optimistic FTRL in Theorem 7.39, for the  $\mathcal{X}$ -player we have

$$\sum_{t=1}^{T} (\ell_t(\boldsymbol{x}_t) - \ell(\boldsymbol{u})) \leq \psi_{\mathcal{X}}(\boldsymbol{u}) + \sum_{t=1}^{T} \left( \langle \boldsymbol{g}_{\mathcal{X},t} - \boldsymbol{g}_{\mathcal{X},t-1}, \boldsymbol{x}_t - \boldsymbol{x}_{t+1} \rangle - \frac{\lambda_{\mathcal{X}}}{2} \|\boldsymbol{x}_t - \boldsymbol{x}_{t+1}\|_{\mathcal{X}}^2 \right), \ \forall \boldsymbol{u} \in \mathcal{X}.$$

From the Fenchel-Young inequality, we have  $\langle \boldsymbol{g}_{\mathcal{X},t} - \boldsymbol{g}_{\mathcal{X},t-1}, \boldsymbol{x}_t - \boldsymbol{x}_{t+1} \rangle \leq \frac{\lambda_{\mathcal{X}}}{4} \|\boldsymbol{x}_t - \boldsymbol{x}_{t+1}\|_{\mathcal{X}}^2 + \frac{1}{\lambda_{\mathcal{X}}} \|\boldsymbol{g}_{\mathcal{X},t} - \boldsymbol{g}_{\mathcal{X},t-1}\|_{\mathcal{X},\star}^2$ . Putting all together, we have

$$\sum_{t=1}^{T} (\ell_t(\boldsymbol{x}_t) - \ell(\boldsymbol{u})) \leq \psi_{\mathcal{X}}(\boldsymbol{u}) + \sum_{t=1}^{T} \left( \frac{1}{\lambda_{\mathcal{X}}} \|\boldsymbol{g}_{\mathcal{X},t} - \boldsymbol{g}_{\mathcal{X},t-1}\|_{\mathcal{X},\star}^2 - \frac{\lambda_{\mathcal{X}}}{4} \|\boldsymbol{x}_t - \boldsymbol{x}_{t+1}\|_{\mathcal{X}}^2 \right), \ \forall \boldsymbol{u} \in \mathcal{X}.$$

Note that there are multiple choices of the coefficient in the Fenchel-Young inequality, but without additional information all choices are equally good.

Now, using the smoothness assumption, for  $t \geq 2$  we have

$$\begin{aligned} \|\boldsymbol{g}_{\mathcal{X},t} - \boldsymbol{g}_{\mathcal{X},t-1}\|_{\mathcal{X},\star}^{2} &= \|\nabla_{\boldsymbol{x}} f(\boldsymbol{x}_{t}, \boldsymbol{y}_{t}) - \nabla_{\boldsymbol{x}} f(\boldsymbol{x}_{t-1}, \boldsymbol{y}_{t-1})\|_{\mathcal{X},\star}^{2} \\ &\leq \left( \|\nabla_{\boldsymbol{x}} f(\boldsymbol{x}_{t}, \boldsymbol{y}_{t}) - \nabla_{\boldsymbol{x}} f(\boldsymbol{x}_{t-1}, \boldsymbol{y}_{t})\|_{\mathcal{X},\star} + \|\nabla_{\boldsymbol{x}} f(\boldsymbol{x}_{t-1}, \boldsymbol{y}_{t}) - \nabla_{\boldsymbol{x}} f(\boldsymbol{x}_{t-1}, \boldsymbol{y}_{t-1})\|_{\mathcal{X},\star} \right)^{2} \\ &\leq 2L_{\mathcal{X}\mathcal{X}}^{2} \|\boldsymbol{x}_{t-1} - \boldsymbol{x}_{t}\|_{\mathcal{X}}^{2} + 2L_{\mathcal{X}\mathcal{Y}}^{2} \|\boldsymbol{y}_{t-1} - \boldsymbol{y}_{t}\|_{\mathcal{Y}}^{2}. \end{aligned}$$

We can proceed in the exact same way for the  $\mathcal{Y}$ -player too.

Summing the regret of the two algorithms, we have

$$\begin{split} \sum_{t=1}^{T} f(\boldsymbol{x}_{t}, \boldsymbol{y}) - \sum_{t=1}^{T} f(\boldsymbol{x}, \boldsymbol{y}_{t}) &\leq \psi_{\mathcal{X}}(\boldsymbol{x}) + \psi_{\mathcal{Y}}(\boldsymbol{y}) + \frac{\|\boldsymbol{g}_{\mathcal{X}, 1}\|_{\mathcal{X}, \star}^{2}}{\lambda_{\mathcal{X}}} + \frac{\|\boldsymbol{g}_{\mathcal{Y}, 1}\|_{\mathcal{Y}, \star}^{2}}{\lambda_{\mathcal{Y}}} \\ &+ \sum_{t=2}^{T} \left( \left( \frac{2L_{\mathcal{X}\mathcal{X}}^{2}}{\lambda_{\mathcal{X}}} + \frac{2L_{\mathcal{X}\mathcal{Y}}^{2}}{\lambda_{\mathcal{Y}}} - \frac{\lambda_{\mathcal{X}}}{4} \right) \|\boldsymbol{x}_{t} - \boldsymbol{x}_{t-1}\|_{\mathcal{X}}^{2} + \left( \frac{2L_{\mathcal{Y}\mathcal{Y}}^{2}}{\lambda_{\mathcal{Y}}} + \frac{2L_{\mathcal{X}\mathcal{Y}}^{2}}{\lambda_{\mathcal{X}}} - \frac{\lambda_{\mathcal{Y}}}{4} \right) \|\boldsymbol{y}_{t} - \boldsymbol{y}_{t-1}\|_{\mathcal{Y}}^{2} \right) . \end{split}$$

Choosing  $\lambda_{\mathcal{X}} \geq 2\sqrt{2}(L_{\mathcal{X}\mathcal{X}} + L_{\mathcal{X}\mathcal{Y}}\alpha)$  and  $\lambda_{\mathcal{Y}} \geq 2\sqrt{2}(L_{\mathcal{Y}\mathcal{Y}} + L_{\mathcal{X}\mathcal{Y}}/\alpha)$  for any  $\alpha > 0$  kills all the terms in the sum. In fact, we have

$$\frac{2L_{\mathcal{X}\mathcal{X}}^2}{\lambda_{\mathcal{X}}} + \frac{2L_{\mathcal{X}\mathcal{Y}}^2}{\lambda_{\mathcal{Y}}} \le \frac{2L_{\mathcal{X}\mathcal{X}}^2}{2\sqrt{2}L_{\mathcal{X}\mathcal{X}}} + \frac{2L_{\mathcal{X}\mathcal{Y}}^2\alpha}{2\sqrt{2}L_{\mathcal{X}\mathcal{Y}}} \le \frac{\lambda_{\mathcal{X}}}{4},$$

and similarly for the other term. One might wonder why we need to introduce  $\alpha$  and if it can be just set to 1. However,  $\alpha$  has units and it allows the sum of the smoothness coefficients with different units, so it is better to keep it around to remember it.

Assuming that the regularizers are bounded over  $\mathcal{X}$  and  $\mathcal{Y}$  and using the usual online-to-batch conversion, we have that the duality gap evaluated at the pair  $\left(\frac{1}{T}\sum_{t=1}^{T}\boldsymbol{x}_{t},\frac{1}{T}\sum_{t=1}^{T}\boldsymbol{y}_{t}\right)$  goes to zero as  $\mathcal{O}(1/T)$  when  $T\to\infty$ . Overall, we can state the following theorem.

**Theorem 12.25.** With the notation in Algorithm 12.6, let  $f: \mathcal{X} \times \mathcal{Y} \to \mathbb{R}$  convex in the first argument and concave in the second, satisfying assumptions (12.7)-(12.10). For a fixed  $\alpha > 0$ , let  $\lambda_{\mathcal{X}} \geq 2\sqrt{2}(L_{\mathcal{X}\mathcal{X}} + L_{\mathcal{X}\mathcal{Y}}\alpha)$  and  $\lambda_{\mathcal{Y}} \geq 2\sqrt{2}(L_{\mathcal{X}\mathcal{X}} + L_{\mathcal{X}\mathcal{Y}}\alpha)$  $2\sqrt{2}(L_{yy}+L_{xy}/\alpha)$ . Let  $\psi_{\mathcal{X}}:X\to\mathbb{R}$  be  $\lambda_{\mathcal{X}}$ -strongly convex w.r.t.  $\|\cdot\|_{\mathcal{X}}$  and  $\psi_{\mathcal{Y}}:Y\to\mathbb{R}$  be  $\lambda_{\mathcal{Y}}$ -strongly convex w.r.t.  $\|\cdot\|_{\mathcal{Y}}$ . Assume that  $\arg\max_{\boldsymbol{y}\in\mathcal{Y}} f(\bar{\boldsymbol{x}}_T,\boldsymbol{y})$  and  $\arg\min_{\boldsymbol{x}\in\mathcal{X}} f(\boldsymbol{x},\bar{\boldsymbol{y}}_T)$  are non-empty. Then, we have

$$\max_{\boldsymbol{y} \in \mathcal{Y}} f(\bar{\boldsymbol{x}}_T, \boldsymbol{y}) - \min_{\boldsymbol{x} \in \mathcal{X}} f(\boldsymbol{x}, \bar{\boldsymbol{y}}_T) \leq \frac{\psi_{\mathcal{X}}(\boldsymbol{x}_T') - \psi_{\mathcal{X}}(\boldsymbol{x}_1) + \psi_{\mathcal{Y}}(\boldsymbol{y}_T') - \psi_{\mathcal{Y}}(\boldsymbol{y}_1) + \frac{\|\boldsymbol{g}_{\mathcal{X},1}\|_{\mathcal{X},\star}^2}{\lambda_{\mathcal{X}}} + \frac{\|\boldsymbol{g}_{\mathcal{Y},1}\|_{\mathcal{Y},\star}^2}{\lambda_{\mathcal{Y}}},$$

for any  $x_T' \in \arg\min_{x \in \mathcal{X}} f(x, \bar{y}_T)$  and  $y_T' \in \arg\max_{y \in \mathcal{Y}} f(\bar{x}_T, y)$ .

Looking back at the proof of the algorithm, we have a faster convergence because regret of one player depends on the "stability" of the other player, measured by the terms  $\|x_t - x_{t-1}\|_{\mathcal{X}}^2$  and  $\|y_t - y_{t-1}\|_{\mathcal{Y}}^2$ . Hence, we have a sort of stabilization loop in which the stability of one algorithm makes the other more stable, that in turn stabilizes the first one even more. Indeed, we can also show that the regret of the two algorithms is not growing over time. Note that such result cannot be obtained just looking at the fact that the sum of the regret does not grow over time.

In fact, setting for example  $\lambda_{\mathcal{X}} \geq 4\sqrt{2}(L_{\mathcal{X}\mathcal{X}} + L_{\mathcal{X}\mathcal{Y}}\alpha)$  and  $\lambda_{\mathcal{Y}} \geq 4\sqrt{2}(L_{\mathcal{Y}\mathcal{Y}} + L_{\mathcal{X}\mathcal{Y}}/\alpha)$ , we have that

$$\frac{2L_{\mathcal{Y}\mathcal{Y}}^2}{\lambda_{\mathcal{Y}}} + \frac{2L_{\mathcal{X}\mathcal{Y}}^2}{\lambda_{\mathcal{X}}} - \frac{\lambda_{\mathcal{Y}}}{4} \le -\frac{\lambda_{\mathcal{Y}}}{8}$$

and

$$\frac{2L_{\mathcal{X}\mathcal{X}}^2}{\lambda_{\mathcal{X}}} + \frac{2L_{\mathcal{X}\mathcal{Y}}^2}{\lambda_{\mathcal{Y}}} - \frac{\lambda_{\mathcal{X}}}{4} \le -\frac{\lambda_{\mathcal{X}}}{8} .$$

Hence, using the fact that the existence of a saddle point  $(x^*, y^*)$  guarantee that  $f(x_t, y^*) - f(x^*, y_t) \ge 0$ , we have

$$\sum_{t=2}^{T} \left( \frac{\lambda_{\mathcal{X}}}{8} \| \boldsymbol{x}_{t} - \boldsymbol{x}_{t-1} \|_{\mathcal{X}}^{2} + \frac{\lambda_{\mathcal{Y}}}{8} \| \boldsymbol{y}_{t} - \boldsymbol{y}_{t-1} \|_{\mathcal{Y}}^{2} \right) \leq \psi_{\mathcal{X}}(\boldsymbol{x}^{\star}) - \psi_{\mathcal{X}}(\boldsymbol{x}_{1}) + \psi_{\mathcal{Y}}(\boldsymbol{y}^{\star}) - \psi_{\mathcal{Y}}(\boldsymbol{y}_{1}) + \frac{\|\boldsymbol{g}_{\mathcal{X},1}\|_{\mathcal{X},\star}^{2}}{\lambda_{\mathcal{X}}} + \frac{\|\boldsymbol{g}_{\mathcal{Y},1}\|_{\mathcal{Y},\star}^{2}}{\lambda_{\mathcal{Y}}}.$$
(12.11)

Plugging this guarantee back in the regret of each algorithm, we have that their regret is bounded and independent of T. From (12.11), we also have that  $\|x_t - x_{t-1}\|_{\mathcal{X}}^2$  and  $\|y_t - y_{t-1}\|_{\mathcal{Y}}^2$  converge 0. Hence, the algorithms are getting more and more stable over time, even if they use constant regularizers.

**Remark 12.26.** Note that the fact that  $\lim_{t\to\infty} \|x_t - x_{t-1}\|_{\mathcal{X}} = 0$  is not enough to infer that  $x_t$  is converging. In fact, it is enough to consider the case of  $x_t = \ln t$ .

Version with Optimistic OMD The exact same reasoning holds for Optimistic OMD, because the key terms of its regret bound are exactly the same of the ones of Optimistic FTRL. To better show this fact, we instantiate the Optimistic OMD with stepsizes equal to  $\frac{1}{\lambda_{\mathcal{X}}}$  and  $\frac{1}{\lambda_{\mathcal{Y}}}$  for  $\mathcal{X}$ -player and  $\mathcal{Y}$ -player respectively. Following the same reasoning as above and the regret bound of Optimistic OMD, we obtain the following theorem. **Theorem 12.27.** With the notation in Algorithm 12.7, let  $f: \mathcal{X} \times \mathcal{Y} \to \mathbb{R}$  convex in the first argument and concave in the second, satisfying assumptions (12.7)-(12.10). For a fixed  $\alpha > 0$ , let  $\lambda_{\mathcal{X}} \geq 2\sqrt{2}(L_{\mathcal{X}\mathcal{X}} + L_{\mathcal{X}\mathcal{Y}}\alpha)$  and  $\lambda_{\mathcal{Y}} \geq 2\sqrt{2}(L_{\mathcal{Y}\mathcal{Y}} + L_{\mathcal{X}\mathcal{Y}}/\alpha)$ . Let  $\psi_{\mathcal{X}}: X \to \mathbb{R}$  be 1-strongly convex w.r.t.  $\|\cdot\|_{\mathcal{X}}$  and  $\psi_{\mathcal{Y}}: Y \to \mathbb{R}$  be 1-strongly convex w.r.t.  $\|\cdot\|_{\mathcal{Y}}$ . Assume  $\max_{\boldsymbol{y} \in \mathcal{Y}} f(\bar{\boldsymbol{x}}_T, \boldsymbol{y})$  and  $\arg\min_{\boldsymbol{x} \in \mathcal{X}} f(\boldsymbol{x}, \bar{\boldsymbol{y}}_T)$  non-empty. Then, we have

$$\max_{\boldsymbol{y}\in\mathcal{Y}} f(\bar{\boldsymbol{x}}_T, \boldsymbol{y}) - \min_{\boldsymbol{x}\in\mathcal{X}} f(\boldsymbol{x}, \bar{\boldsymbol{y}}_T) \leq \frac{B_{\psi_{\mathcal{X}}}(\boldsymbol{x}_T'; \boldsymbol{x}_1) + B_{\psi_{\mathcal{Y}}}(\boldsymbol{y}_T'; \boldsymbol{y}_1) + \frac{\|\boldsymbol{g}_{\mathcal{X},1}\|_{\mathcal{X},\star}^2}{\lambda_{\mathcal{X}}} + \frac{\|\boldsymbol{g}_{\mathcal{Y},1}\|_{\mathcal{Y},\star}^2}{\lambda_{\mathcal{Y}}}}{T},$$

for any  $x'_T \in \arg\min_{x \in \mathcal{X}} f(x, \bar{y}_T)$  and  $y'_T \in \arg\max_{y \in \mathcal{Y}} f(\bar{x}_T, y)$ .

# Algorithm 12.7 Solving Saddle-Point Problems with Optimistic OMD

```
Require: \lambda_{\mathcal{X}} > 0, \lambda_{\mathcal{Y}} > 0, x_1 \in \mathcal{X}, y_1 \in \mathcal{Y}

1: g_{\mathcal{X},0} = 0, g_{\mathcal{Y},0} = 0

2: for t = 1, \dots, T do

3: Set g_{\mathcal{X},t} = \nabla_{\boldsymbol{x}} f(\boldsymbol{x}_t, \boldsymbol{y}_t)

4: Set g_{\mathcal{Y},t} = -\nabla_{\boldsymbol{y}} f(\boldsymbol{x}_t, \boldsymbol{y}_t)

5: \boldsymbol{x}_{t+1} = \operatorname{argmin}_{\boldsymbol{x} \in \mathcal{X}} \langle 2\boldsymbol{g}_{\mathcal{X},t} - \boldsymbol{g}_{\mathcal{X},t-1}, \boldsymbol{x} \rangle + \lambda_{\mathcal{X}} B_{\psi_{\mathcal{X}}}(\boldsymbol{x}; \boldsymbol{x}_t)

6: \boldsymbol{y}_{t+1} = \operatorname{argmin}_{\boldsymbol{y} \in \mathcal{Y}} \langle 2\boldsymbol{g}_{\mathcal{Y},t} - \boldsymbol{g}_{\mathcal{Y},t-1}, \boldsymbol{y} \rangle + \lambda_{\mathcal{Y}} B_{\psi_{\mathcal{Y}}}(\boldsymbol{y}; \boldsymbol{y}_t)

7: end for

8: return \bar{\boldsymbol{x}}_T = \frac{1}{T} \sum_{t=1}^T \boldsymbol{x}_t, \bar{\boldsymbol{y}}_T = \frac{1}{T} \sum_{t=1}^T \boldsymbol{y}_t
```

**Example 12.28.** Consider the bilinear saddle point problem

$$\min_{\boldsymbol{x} \in \mathcal{X}} \max_{\boldsymbol{y} \in \mathcal{Y}} \boldsymbol{x}^{\top} A \boldsymbol{y} .$$

In this case, we have that  $\nabla_{\boldsymbol{x}} f(\boldsymbol{x}, \boldsymbol{y}) = A \boldsymbol{y}$ ,  $\nabla_{\boldsymbol{y}} f(\boldsymbol{x}, \boldsymbol{y}) = A^{\top} \boldsymbol{x}$ ,  $L_{\mathcal{X}\mathcal{X}} = 0$ ,  $L_{\mathcal{Y}\mathcal{Y}} = 0$ , and  $L_{\mathcal{X}\mathcal{Y}} = \|A\|_{op}$  where  $\|\cdot\|_{op}$  is the operator norm of the matrix A. The specific shape of the operator norm depends on the norms we use on  $\mathcal{X}$  and  $\mathcal{Y}$ . For example, we choose the Euclidean norm on both  $\mathcal{X}$  and  $\mathcal{Y}$ , the operator norm of A is the largest singular value of A. On the other hand, if  $\mathcal{X} = \Delta^{n-1}$  and  $\Delta^{m-1}$  as in the two-person zero-sum games, then the operator norm of a matrix A is the maximum absolute value of the entries of A.

# 12.6 Prescient Online Mirror Descent and Be-The-Regularized-Leader

The above result is interesting from a game-theoretic point of view, because it shows that two player can converge to an equilibrium without any "communication", if instead we only care about converging to the saddle point, we can easily do better. In fact, we can use the fact that it is fine if one of the two players "cheats" by looking at the loss at the beginning of each round, making its regret non-positive. However, as discussed in Remark 12.17, this will change the oracle, because now one of the algorithms needs to access the functions rather than only their gradients.

For example, we saw the use of Best Response. However, Best Response only guarantees non-positive regret, while for the optimistic proof above we need some specific negative terms. It turns out we can achieve them with another algorithm: Prescient Online Mirror Descent, that predicts in each round with  $x_t \in \operatorname{argmin}_{x \in \mathcal{V}} \ell_t(x) + \frac{1}{\eta_t} B_{\psi}(x; x_{t-1})$ .

**Theorem 12.29.** Let  $\psi: \mathcal{X} \to \mathbb{R}$  differentiable in int  $\mathcal{X}$ , closed, and strictly convex. Let  $\mathcal{V} \subseteq \mathcal{X}$  a non-empty closed convex set. Assume  $\mathbf{x}_t \in \text{int } \mathcal{X}$ ,  $\ell_t$  subdifferentiable in  $\mathcal{V}$ , and  $\eta_{t+1} \leq \eta_t$ , for  $t = 1, \ldots, T$ . Then,  $\forall \mathbf{u} \in \mathcal{V}$ , Algorithm 12.8 satisfies

$$\sum_{t=1}^{T} \ell_t(\boldsymbol{x}_t) - \sum_{t=1}^{T} \ell_t(\boldsymbol{u}) \le \max_{1 \le t \le T-1} \frac{B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_t)}{\eta_T} - \sum_{t=1}^{T} \frac{1}{\eta_t} B_{\psi}(\boldsymbol{x}_t, \boldsymbol{x}_{t-1}) .$$

# Algorithm 12.8 Prescient Online Mirror Descent

**Require:** Non-empty closed convex  $\mathcal{V} \subset \mathcal{X} \subseteq \mathbb{R}^d$ ,  $\psi : \mathcal{X} \to \mathbb{R}$  strictly convex and differentiable on int  $\mathcal{X}$ ,  $x_0 \in \operatorname{int} \mathcal{X}$ ,  $\eta_1, \ldots, \eta_T > 0$ 

1: for t = 1 to T do

2: Receive  $\ell_t: \mathcal{V} \to \mathbb{R}$  subdifferentiable in  $\mathcal{V}$ 

3:  $\boldsymbol{x}_t \in \operatorname{argmin}_{\boldsymbol{x} \in \mathcal{V}} \ \ell_t(\boldsymbol{x}) + \frac{1}{n_t} B_{\psi}(\boldsymbol{x}; \boldsymbol{x}_{t-1})$ 

4: Pay  $\ell_t(\boldsymbol{x}_t)$ 

5: end for

Moreover, if  $\eta_t$  is constant, i.e.,  $\eta_t = \eta \ \forall t = 1, \cdots, T$ , we have

$$\sum_{t=1}^T (\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) \leq \frac{B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_0)}{\eta} - \frac{1}{\eta} \sum_{t=1}^T B_{\psi}(\boldsymbol{x}_t, \boldsymbol{x}_{t-1}) .$$

*Proof.* From the first-order optimality condition on the update, we have that there exists  $g_t \in \partial \ell_t(x_t)$  such

$$\langle \eta_t \boldsymbol{g}_t + \nabla \psi(\boldsymbol{x}_t) - \nabla \psi(\boldsymbol{x}_{t-1}), \boldsymbol{u} - \boldsymbol{x}_t \rangle \ge 0, \quad \forall \boldsymbol{u} \in \mathcal{V}.$$

Hence, we have

$$\eta_t(\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) \leq \langle \eta_t \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{u} \rangle = \langle \nabla \psi(\boldsymbol{x}_{t-1}) - \nabla \psi(\boldsymbol{x}_t), \boldsymbol{x}_t - \boldsymbol{u} \rangle + \langle \eta_t \boldsymbol{g}_t + \nabla \psi(\boldsymbol{x}_t) - \nabla \psi(\boldsymbol{x}_{t-1}), \boldsymbol{x}_t - \boldsymbol{u} \rangle \\
\leq \langle \nabla \psi(\boldsymbol{x}_{t-1}) - \nabla \psi(\boldsymbol{x}_t), \boldsymbol{x}_t - \boldsymbol{u} \rangle \\
= B_{\psi}(\boldsymbol{u}, \boldsymbol{x}_{t-1}) - B_{\psi}(\boldsymbol{u}, \boldsymbol{x}_t) - B_{\psi}(\boldsymbol{x}_t, \boldsymbol{x}_{t-1}),$$

where in the last equality we used Lemma 6.7. Dividing by  $\eta_t$  and summing over  $t=1,\ldots,T$ , we have

$$\sum_{t=1}^{T} (\ell_{t}(\boldsymbol{x}_{t}) - \ell_{t}(\boldsymbol{u})) \leq \sum_{t=1}^{T} \left(\frac{1}{\eta_{t}} B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_{t-1}) - \frac{1}{\eta_{t}} B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_{t})\right) - \sum_{t=1}^{T} \frac{1}{\eta_{t}} B_{\psi}(\boldsymbol{x}_{t}, \boldsymbol{x}_{t-1})$$

$$= \frac{1}{\eta_{1}} B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_{0}) - \frac{1}{\eta_{T}} B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_{T}) + \sum_{t=1}^{T-1} \left(\frac{1}{\eta_{t+1}} - \frac{1}{\eta_{t}}\right) B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_{t}) - \sum_{t=1}^{T} \frac{1}{\eta_{t}} B_{\psi}(\boldsymbol{x}_{t}, \boldsymbol{x}_{t-1})$$

$$\leq \frac{1}{\eta_{1}} D^{2} + D^{2} \sum_{t=1}^{T-1} \left(\frac{1}{\eta_{t+1}} - \frac{1}{\eta_{t}}\right) - \sum_{t=1}^{T} \frac{1}{\eta_{t}} B_{\psi}(\boldsymbol{x}_{t}, \boldsymbol{x}_{t-1})$$

$$= \frac{1}{\eta_{1}} D^{2} + D^{2} \left(\frac{1}{\eta_{T}} - \frac{1}{\eta_{1}}\right) - \sum_{t=1}^{T} \frac{1}{\eta_{t}} B_{\psi}(\boldsymbol{x}_{t}, \boldsymbol{x}_{t-1})$$

$$= \frac{D^{2}}{\eta_{T}} - \sum_{t=1}^{T} \frac{1}{\eta_{t}} B_{\psi}(\boldsymbol{x}_{t}, \boldsymbol{x}_{t-1}),$$

where we denoted by  $D^2 = \max_{1 \le t \le T-1} B_{\psi}(\boldsymbol{u}; \boldsymbol{x}_t)$ .

The second statement is left as exercise.

The regret of Prescient Online Mirror Descent contains the negative terms we needed from the optimistic algorithms.

Analogously, we can obtain a version of FTRL that uses the knowledge of the current loss: Be-The-Regularized-Leader (BTRL), that predicts in each time step with  $x_t \in \operatorname{argmin}_{x \in \mathcal{V}} \psi_t(x) + \sum_{i=1}^t \ell_i(x)$ .

In the case that  $\psi_t \equiv 0$ , then Be-The-Regularized-Leader becomes the Be-The-Leader algorithm. BTRL can be thought as Optimistic FTRL where  $\tilde{\ell}_t = \ell_t$ . Hence, from the regret of Optimistic FTRL in Theorem 7.39, we immediately have the following theorem.

#### Algorithm 12.9 Be-the-Regularized-Leader Algorithm

**Require:** Non-empty closed convex  $\mathcal{V} \subset \mathcal{X} \subseteq \mathbb{R}^d$ ,  $\psi_1, \dots, \psi_T$  regularizers

- 1: for t = 1 to T do
- 2: Receive  $\ell_t: \mathcal{V} \to \mathbb{R}$
- 3:  $\boldsymbol{x}_t \in \operatorname{argmin}_{\boldsymbol{x} \in \mathcal{V}} \ \psi_t(\boldsymbol{x}) + \sum_{i=1}^t \ell_i(\boldsymbol{x})$
- 4: Pay  $\ell_t(\boldsymbol{x}_t)$
- 5: end for

**Theorem 12.30.** Let  $V \subset \mathbb{R}^d$  be convex, closed, and non-empty. Assume for t = 1, ..., T that  $\psi_t + \sum_{i=1}^t \ell_i$  is proper, closed, and  $\lambda_t$ -strongly convex w.r.t.  $\|\cdot\|$ . Then, for all  $\mathbf{u} \in V$ , Algorithm 12.9 satisfies

$$\sum_{t=1}^{T} \ell(\boldsymbol{x}_{t}) + \sum_{t=1}^{T} \ell_{t}(\boldsymbol{u}) \leq \psi_{T+1}(\boldsymbol{u}) - \psi_{1}(\boldsymbol{x}_{1}) + \sum_{t=1}^{T} \left( -\frac{\lambda_{t}}{2} \|\boldsymbol{x}_{t} - \boldsymbol{x}_{t+1}\|^{2} + \psi_{t}(\boldsymbol{x}_{t+1}) - \psi_{t+1}(\boldsymbol{x}_{t+1}) \right) .$$

**Remark 12.31.** In the Be-The-Leader algorithm, if all the  $\lambda_t = 0$ , then the theorem states that the regret is non-positive.

Notably, the non-negative gradients terms are missing in the bound of BTRL, but we still have the negative ones associated to the change in  $x_t$ .

Using, for example, BTRL for the  $\mathcal{X}$ -player and Optimistic FTRL for the  $\mathcal{Y}$ -player, we have

$$\sum_{t=1}^{T} f(\boldsymbol{x}_{t}, \boldsymbol{y}) - \sum_{t=1}^{T} f(\boldsymbol{x}, \boldsymbol{y}_{t}) \leq \psi_{\mathcal{X}}(\boldsymbol{x}) + \psi_{\mathcal{Y}}(\boldsymbol{y}) + \frac{\|\boldsymbol{g}_{1}^{Y}\|_{\mathcal{Y}, \star}^{2}}{\lambda_{\mathcal{Y}}} + \sum_{t=2}^{T} \left( \left( \frac{2L_{\mathcal{X}\mathcal{Y}}^{2}}{\lambda_{\mathcal{Y}}} - \frac{\lambda_{\mathcal{X}}}{4} \right) \|\boldsymbol{x}_{t} - \boldsymbol{x}_{t-1}\|_{\mathcal{X}}^{2} + \left( \frac{2L_{\mathcal{Y}\mathcal{Y}}^{2}}{\lambda_{\mathcal{Y}}} - \frac{\lambda_{\mathcal{Y}}}{4} \right) \|\boldsymbol{y}_{t} - \boldsymbol{y}_{t-1}\|_{\mathcal{Y}}^{2} \right).$$

# 12.7 History Bits

Theorem 12.3 is Rockafellar [1970, Lemma 36.2].

The proof of Theorem 12.13 is from Liu and Orabona [2022] and in turn is based on the one in Abernethy and Wang [2017]: Liu and Orabona [2022] stressed the dependency of the regret on a competitor that can be useful for refined bounds. Different variant of this theorem are known in the game theory community as "Folk Theorems", because such result was widely known among game theorists in the 1950s, even though no one had published it.

The celebrated minimax theorem for zero-sum two-person games was first discovered by John von Neumann in the 1920s [Neumann, 1928, Neumann and Morgenstern, 1944]. The version stated here is a simplification of the generalization due to Sion [1958]. The proof here is from Abernethy and Wang [2017]. A similar proof is in Cesa-Bianchi and Lugosi [2006] based on a discretization of the space that in turn is based on the one in Freund and Schapire [1996, 1999b].

Algorithms 12.2 and 12.3 are a generalization of the algorithm for boosting in Freund and Schapire [1996, 1999b]. Algorithm 12.2 was also used in Abernethy and Wang [2017] to recover variants of the Frank-Wolfe algorithm [Frank and Wolfe, 1956].

It is not clear who invented alternation: It was a known trick used in implementations of CFR for the computer poker competition from 2010 or so<sup>1</sup>. Note that in CFR the method of choice is Regret Matching [Hart and Mas-Colell, 2000]. However, Kroer [2020] empirically shows that alternation improves a lot even OGD for solving bilinear games. Tammelin et al. [2015] explicitly include this trick in their implementation of an improved version of CFR called CFR+, claiming that it would still guarantee convergence. However, Farina et al. [2019a] pointed out that averaging of the iterates in alternation might not produce a solution to the min-max problem, providing a counterexample. Theorem 12.18 is from Burch et al. [2019].

<sup>&</sup>lt;sup>1</sup>Christian Kroer, 2021, personal communication.

There is also a complementary view on alternation: Zhang et al. [2021] link alternating updates to Gauss-Seidel methods in numerical linear algebra, in contrast to the simultaneous updates of the Jacobi method. Also, they provide a good review of the optimization literature on the advantages of alternation, but this paper and the papers they cite do not seem to be aware of the use of alternation in CFR.

The reduction from boosting to learning with expert is from Freund and Schapire [1996]. It seems<sup>2</sup> that the question if a weak learner can be boosted into a strong learner was originally posed by Kearns and Valiant [1988] (see also Kearns [1988]). It was answered in the positive by Schapire [1990]. The AdaBoost algorithm is from Freund and Schapire [1995, 1997]. The idea of using algorithms that guarantee a KL regret bound in (12.6) is from Luo and Schapire [2014].

Daskalakis et al. [2011] proposed the first no-regret algorithm that achieved a rate of  $\mathcal{O}(\frac{\ln T}{T})$  for the duality gap when used by the two players of a zero-sum game without any communication between the players. However, the algorithm was rather complex and they posed the problem of obtaining the same or faster rate with a simpler algorithm. Rakhlin and Sridharan [2013a] solved this problem showing that two Optimistic OMD algorithms can solve the problem in a simpler way. Theorems 12.25 and 12.27 derive directly from Rakhlin and Sridharan [2013a, Corollary 5]. For some reason Rakhlin and Sridharan [2013a, Corollary 5] was missed in recent years, so the  $\mathcal{O}(1/T)$  convergence for smooth saddle-point problems using optimistic gradient descent/ascent has been rediscovered a number of times [e.g., Hsieh et al., 2019, Mokhtari et al., 2020] However, the optimistic gradient descent/ascent for saddle-point problems is much older: It was proposed for the first time by Popov [1980], as a modification of the Arrow-Hurwicz method. Roughly 30 years later, the optimistic algorithms were rediscovered, first as pure online learning algorithms [Chiang et al., 2012, Rakhlin and Sridharan, 2013b] and then used to solve saddle-point problems [Rakhlin and Sridharan, 2013a].

The possibility to achieve constant regret for each player observed after Theorem 12.25 is from Luo [2022].

The use of Prescient Online Mirror Descent in saddle point optimization is from Wang et al. [2021], but when renaming  $x_t$  to  $x_{t+1}$  it is also equivalent to implicit online mirror descent [Kivinen and Warmuth, 1997, Kulis and Bartlett, 2010, Campolongo and Orabona, 2020]. Theorem 12.29 is from the guarantee of implicit online mirror descent in Campolongo and Orabona [2020].

There is also a tight connection between optimistic updates using the previous gradients and classic approaches to solve saddle-point optimization. In fact, Gidel et al. [2019] showed that using two optimistic gradient descent algorithms to solve a saddle point problems can be seen as a variant of the Extra-gradient updates [Korpelevich, 1976], while Mokhtari et al. [2020] show that they can be interpreted as an approximated proximal point algorithm.

For generic saddle-point problems, Popov [1980] proved the asymptotic convergence of the iterates when using two optimistic OGD algorithms. This old result was unknown to the majority of the community until recently and it implies some later weaker results [e.g., Daskalakis et al., 2018]. The extension to the Mirror Descent case was done by Semenov [2017] to solve the more general problem of variational inequalities, but only for distance generating functions that are differentiable on the entire feasible set.<sup>3</sup> This means that this proof does not cover the optimistic exponentiated gradient. In turn, this little known result was also recently rediscovered [e.g., Lee et al., 2021, Theorem 4]. Hsieh et al. [2021, Theorem 7] proved the asymptotic convergence of the last iterate for Optimistic FTRL with linear losses and an adaptive regularization weight, assuming either strict convexity/concavity or that the regularizer to be differentiable on the entire domain. Note that the proof in Hsieh et al. [2021, Theorem 7] can be easily adapted to prove the same result for optimistic OMD with a fixed and small enough learning rate. Lei et al. [2021] prove the asymptotic convergence of optimistic exponentiated gradient for saddle-point problems, under the assumption that some of the optimality conditions are satisfied in a strict way.

For the specific case of bilinear games, stronger results can be proven on the last-iterate convergence. Liang and Stokes [2019] proved that if the matrix A is square, full-rank, and the problem unconstrained, then the iterates of two Optimistic OGD will converge exponentially fast to the saddle point in the origin. Daskalakis and Panageas [2019] proved the asymptotic convergence of optimistic OMD/FTRL Exponentiated Gradient with fixed stepsize for bilinear games over probability simplexes, assuming a unique saddle point. Wei et al. [2021] proved an exponential rate for the same algorithm under the same assumptions. Hsieh et al. [2021, Theorem 8] removed the unique saddle

<sup>&</sup>lt;sup>2</sup>I could not verify this claim because I could not find the paper anywhere.

<sup>&</sup>lt;sup>3</sup>Equation 17 in Semenov [2017] needs the fact that the distance generating function is continuously differentiable everywhere for a limit operation. This assumption is not stated, making the proof essentially wrong, for example, for the entropy function. As far as I know, no one had realized this issue in that paper before.

point assumption, proving asymptotic convergence for Optimistic FTRL with entropic regularization and an adaptive regularization weight. Once again, this proof can be easily modified to prove the same result for optimistic OMD with a fixed and small enough learning rate.

# 12.8 Exercises

**Problem 12.1.** *Prove Lemma 12.11.* 

**Problem 12.2.** Let f(x, y) be a convex-concave function, Lipschitz with respect to both variables. Use two FTRL algorithms to find the saddle-point, using as regularizers  $\psi_t(x) \propto \sqrt{t}\psi(x)$ , where  $\psi$  is differentiable and 1-strongly convex with respect to a norm  $\|\cdot\|$ . Then, using the inequality in Exercise 7.2, show that the trajectory of the iterates of the above strategy are bounded on any convex-concave saddle-point problem with at least one saddle-point, even in unbounded domains and any number of dimensions.

# Chapter 13

# Sequential Investment and Universal Portfolio Algorithms

We now describe another online learning problem: Sequential investment in a market with  $d \geq 2$  stocks. The behavior of the market is specified by arbitrarily chosen non-negative market gains vectors  $\boldsymbol{w}_1, \dots, \boldsymbol{w}_T$ , each of them in  $\mathbb{R}^d_{\geq 0}$ . The coordinates of the market gains vectors represent the ratio between closing and opening price for the stocks. In this game, each day we allocate our wealth buying a number of stocks and at the end of the day we sell all the stocks. An investment strategy is specified by a vector  $\boldsymbol{x}_t \in \mathbb{R}^d$ , where  $0 \leq x_{t,i} \leq 1$  and  $\|\boldsymbol{x}_t\|_1 = 1$ , and its elements specifies the fraction of the wealth invested on each stock at time t. We will also assume that the wealth of the investor is infinitely divisible. Hence, assuming an initial wealth of \$1, our wealth at the end of round T is

Wealth<sub>T</sub> = 
$$\sum_{i=1}^{d} \text{Wealth}_{T-1} w_{T,i} x_{T,i} = \text{Wealth}_{T-1} \langle \boldsymbol{w}_{T}, \boldsymbol{x}_{T} \rangle = \prod_{t=1}^{T} \langle \boldsymbol{w}_{t}, \boldsymbol{x}_{t} \rangle$$
.

To define a regret, we have to decide what is the class of comparators. Here, we compare with the *best constantly rebalanced portfolio*. A constantly rebalanced portfolio follows the same strategy we use, but its allocation of the stocks is the same on each time step. Denoting by  $\boldsymbol{u}$  the vector in the simplex of the constantly rebalanced portfolio and initial wealth of \$1, its wealth is Wealth $_T(\boldsymbol{u}) = \prod_{t=1}^T \langle \boldsymbol{w}_t, \boldsymbol{u} \rangle$ .

Given the multiplicative nature of this game, difference of wealths do not make much sense. Hence, we consider the ratio of the wealth of the best constantly rebalanced portfolio and the one of the algorithm or equivalently the difference of the logarithms:

$$\operatorname{Regret}_{T}(\boldsymbol{u}) = \ln \operatorname{Wealth}_{T}(\boldsymbol{u}) - \ln \operatorname{Wealth}_{T} = \sum_{t=1}^{T} \ln \langle \boldsymbol{w}_{t}, \boldsymbol{u} \rangle - \sum_{t=1}^{T} \ln \langle \boldsymbol{w}_{t}, \boldsymbol{x}_{t} \rangle.$$
 (13.1)

Rewritten in this way, it should be clear that this game is just an online convex optimization game where  $\mathcal{V} = \Delta^{d-1}$  and the convex losses are  $\ell_t(\boldsymbol{x}) = -\ln\langle \boldsymbol{w}_t, \boldsymbol{x} \rangle$ .

We will say that a portfolio algorithm is **universal** if the regret against any constantly rebalanced portfolio and with any sequence of market gain vectors is sublinear in time, that is, if the algorithm has no regret.

Why Constantly Rebalanced Portfolios? The class of strategy has advantages that are not immediate to see. First of all, despite of the word "constant" this strategy is a very active one and very different from the buy-and-hold one that consists in buying a set of stocks in the first round and selling them at the end of the game. Let's consider an example that clearly shows the advantage of the constant rebalanced portfolio. Consider only 2 stocks with a sequence of market vectors equal to  $(1, \frac{1}{2}), (1, 2), (1, \frac{1}{2}), (1, 2), \ldots$  In the long run none of these two stocks yield any value and so the buy-and-hold strategy does not bring any growth. Instead, the best constantly rebalanced portfolio here is  $u = (\frac{1}{2}, \frac{1}{2})$  and it gives an exponentially increasing wealth of  $(\frac{9}{8})^{t/2} \approx 1.06^t$ . If it seems slow, we need to realize that this means that you would more than double your wealth every 12 days.

Another motivation to compare with constantly rebalanced portfolios is that it can be shown that in the case the market vectors are i.i.d. from some fixed (unknown) distribution, then the constantly rebalanced portfolio is asymptotically optimal.

#### **13.1** Portfolio Selection with Exponentiated Gradient

Given that the problem in (13.1) is an online convex optimization game, we could think of using any of the algorithms we saw till now. In particular, given that the feasible set is the probability simplex and that the loss are convex, we can try to use Exponentiated Gradient. However, this problem turns out to be particularly challenging. In fact, the loss functions are not Lipschitz, so their gradients are unbounded.

In fact, using the upper bound to the regret of exponentiated gradient, we have

$$\sum_{t=1}^T \ln \langle \boldsymbol{w}_t, \boldsymbol{u} \rangle - \sum_{t=1}^T \ln \langle \boldsymbol{w}_t, \boldsymbol{x}_t \rangle \leq \frac{\ln d}{\eta} + \frac{\eta}{2} \sum_{t=1}^T \|\boldsymbol{g}_t\|_{\infty}^2 = \frac{\ln d}{\eta} + \frac{\eta}{2} \sum_{t=1}^T \frac{\|\boldsymbol{w}_t\|_{\infty}^2}{(\langle \boldsymbol{x}_t, \boldsymbol{w}_t \rangle)^2}.$$

The terms in the sum are potentially unbounded, so we will assume that the market gains are in the range [c, C]. In this way, we have  $\frac{\|\boldsymbol{w}_t\|_{\infty}^2}{(\langle \boldsymbol{x}_t, \boldsymbol{w}_t \rangle)^2} \leq \frac{C^2}{c^2}$ . Setting the learning rate to  $\eta = \frac{\sqrt{\ln d}}{\frac{C}{c}\sqrt{T}}$ , we obtain a regret upper bound of

$$\frac{C}{c}\sqrt{T\ln d}.$$
 (13.2)

While the average regret is vanishing, we had to use the additional assumption on the market gains so the resulting algorithm is not universal, according to our definition above. In the next section, we will see that we can remove the constraint on the market gains and also achieve a much better dependency in T.

#### **13.2** Universal Portfolio Selection with F-Weighted Portfolio Algorithms

### Algorithm 13.1 F-Weighted Portfolio Selection

**Require:**  $F: \Delta^{d-1} \to \mathbb{R}$  probability density function

- 1: Wealth<sub>0</sub> = 1
- 2: **for** t = 1 **to** T **do** 3: Set  $\boldsymbol{x}_t = \frac{\int_{\Delta^{d-1}} \boldsymbol{x} \operatorname{Wealth}_{t-1}(\boldsymbol{x}) dF(\boldsymbol{x})}{\int_{\Delta^{d-1}} \operatorname{Wealth}_{t-1}(\boldsymbol{x}) dF(\boldsymbol{x})}$
- Receive  $\boldsymbol{w}_t \in \mathbb{R}^d_{\geq 0}$
- Wealth<sub>t</sub> = Wea $\overline{\text{lth}}_{t-1}\langle \boldsymbol{w}_t, \boldsymbol{x}_t \rangle$
- 6: end for

To solve the problem of the unbounded gradients, we will consider a different strategy. In particular, we will use the F-weighted portfolio algorithms [Cover, 1991], in Algorithm 13.1, that predict at each step with

$$\boldsymbol{x}_t = \frac{\int_{\Delta^{d-1}} \boldsymbol{x} \operatorname{Wealth}_{t-1}(\boldsymbol{x}) dF(\boldsymbol{x})}{\int_{\Delta^{d-1}} \operatorname{Wealth}_{t-1}(\boldsymbol{x}) dF(\boldsymbol{x})},$$

where  $F:\Delta^{d-1}\to\mathbb{R}$  is a probability density function. To understand this formula, consider a generic constantly rebalanced portfolio allocation  $x \in \Delta^{d-1}$  whose wealth after t-1 rounds is Wealth<sub>t-1</sub>(x). Now, consider a probability distribution of all the possible constantly rebalanced portfolios proportional to Wealth<sub>t-1</sub>(x)F(x), where F(x) is a probability distribution. We have that  $x_t$  defined above is nothing else than the average portfolio according to this distribution. Hence, we give more importance in the average to successful portfolios that are also weighted highly by the distribution F.

The above strategy also gives us a closed form expression for the wealth of the algorithm:

Wealth<sub>t</sub> = 
$$\int_{\Delta^{d-1}} \text{Wealth}_t(\boldsymbol{x}) \, dF(\boldsymbol{x}),$$

that is, the wealth of the F-weighted portfolio is the average wealth of constantly rebalanced portfolios according to the distribution F. Let's prove this expression by induction. At t=1 the claim is true, so let's assume it is true at t-1 and let's prove it at t. We have

Wealth<sub>t</sub> = Wealth<sub>t-1</sub>
$$\langle \boldsymbol{w}_t, \boldsymbol{x}_t \rangle = \int_{\Delta^{d-1}} \text{Wealth}_{t-1}(\boldsymbol{x}) \, dF(\boldsymbol{x}) \frac{\int_{\Delta^{d-1}} \langle \boldsymbol{w}_t, \boldsymbol{x} \rangle \, \text{Wealth}_{t-1}(\boldsymbol{x}) \, dF(\boldsymbol{x})}{\int_{\Delta^{d-1}} \text{Wealth}_{t-1}(\boldsymbol{x}) \, dF(\boldsymbol{x})}$$

$$= \int_{\Delta^{d-1}} \text{Wealth}_t(\boldsymbol{x}) \, dF(\boldsymbol{x}) . \tag{13.3}$$

Cover and Ordentlich [1996] proved the universal property using two possible settings of F: the Dirichlet  $(1/2,\ldots,1/2)$  distribution  $(F(\boldsymbol{x}) = \frac{\Gamma(d/2)}{\pi^{d/2}} \prod_{i=1}^d \frac{1}{\sqrt{x_i}}$  for  $\boldsymbol{x} \in \Delta^{d-1})$  and the uniform distribution. For these two distribution they proved the following regret upper bounds.

**Theorem 13.1.** Consider the F-weighted portfolio strategy and an arbitrary sequence of market gains  $\mathbf{w}_t \in \mathbb{R}^d_{\geq 0}$  for  $t = 1, \dots, T$ .

• If F is equal to the Dirichlet (1/2, ..., 1/2) distribution, then we have

$$\operatorname{Regret}_{T} = \operatorname{ln} \operatorname{Wealth}_{T}(\boldsymbol{u}) - \operatorname{ln} \operatorname{Wealth}_{T} \leq \operatorname{ln} \frac{\sqrt{\pi} \Gamma\left(T + \frac{d}{2}\right)}{\Gamma\left(\frac{d}{2}\right) \Gamma\left(T + \frac{1}{2}\right)} \leq \frac{d-1}{2} \ln(2(T+1)),$$

where  $\Gamma(x) = \int_0^{+\infty} t^{x-1} \exp(-t) dt$  is the gamma function.

• If F is equal to the uniform distribution, then we have

$$\operatorname{Regret}_T = \ln \operatorname{Wealth}_T(\boldsymbol{u}) - \ln \operatorname{Wealth}_T \le \ln \binom{T+d-1}{d-1} \le (d-1) \left( \ln \left( \frac{T}{d-1} + 1 \right) + 1 \right) .$$

Observe that both prediction strategies assure that we never produce a vector where the loss is infinite and it allows us to show a vanishing average regret. Moreover, it can be shown that this first regret upper bound is optimal up to constant additive terms. Also, the proof shows that regret upper bounds are essentially tight in the case that in each round the market gains are vectors with all zeros but one coordinate with a '1'.

To prove this theorem, we will need some tools from information theory.

# 13.3 Information Theory Bits

We will need some basic result from information theory and in particular upper bounds used in the method of types.

**Definition 13.2** (Type of a sequence of symbols). Consider a sequence of T symbols  $\mathbf{x} = (x_1, \dots, x_T)$ , where each  $x_t \in \{1, \dots, d\}$ . The **type** of the sequence is the vector  $\mathbf{n}$  of the fractions of times each symbol appears, i.e.,  $\mathbf{n} = [N(1; \mathbf{x})/T, \dots, N(d; \mathbf{x})/T]$ , where  $N(j; \mathbf{x}) := \sum_{t=1}^{T} \mathbf{1}[x_t = j]$ .

First, we prove the following lemma.

**Lemma 13.3.** Let  $T \ge 1$ ,  $x \in \mathbb{R}^d_{\ge 0}$  such that  $\sum_{i=1}^d x_i = T$ ,  $u \in \mathbb{R}^d_{\ge 0}$ , and  $\sum_{i=1}^d u_i = 1$ . Then, we have

$$\prod_{i=1}^{d} u_i^{x_i} \le \prod_{i=1}^{d} \left(\frac{x_i}{T}\right)^{x_i}.$$

*Proof.* If there exists i such that  $u_i^{x_i} = 0$ , the inequality is verified. So, in the following we assume that  $u_i^{x_i} \neq 0$  for  $i = 1, \ldots, d$ . So, if for a given i we have  $u_i = 0$  we must have  $x_i = 0$  as well. Hence, we have

$$\prod_{i=1}^{d} u_i^{x_i} = \prod_{i:u_i \neq 0} u_i^{x_i} = \prod_{i:u_i \neq 0} e^{x_i \ln u_i} = \prod_{i:u_i \neq 0} e^{T\left(\frac{x_i}{T} \ln \frac{x_i}{T} + \frac{x_i}{T} \ln \frac{u_i T}{x_i}\right)} = \prod_{i:u_i \neq 0} e^{T(-H(\boldsymbol{x}/T) - D(\boldsymbol{x}/T;\boldsymbol{u}))}$$

$$\leq \prod_{i:u_i \neq 0} e^{-TH(\boldsymbol{x}/T)} = \prod_{i=1}^{d} \left(\frac{x_i}{T}\right)^{x_i},$$

where  $0 \ln 0 := 0$ ,  $H(\boldsymbol{x}) := -\sum_{i=1}^{d} x_i \ln x_i$  is the entropy, and  $D(\boldsymbol{x}; \boldsymbol{y}) := \sum_{i=1}^{d} x_i \ln \frac{x_i}{y_i}$  is the KL divergence, and the inequality is due to the fact that the KL divergence is non-negative.

**Theorem 13.4.** Consider an alphabet of d symbols and consider the set of all the sequences of length T symbols. Let the set of all possible types of these sequence be  $Q \subset \Delta^{d-1}$ . Denote by  $\mathrm{Type}_T(n)$  the set of all the sequences of length T symbols with a type n, that is  $\mathrm{Type}_T(n) := \{x \in \{1, \ldots, d\}^T : x \text{ has type } n\}$ . Then, for any  $u \in Q$ , we have  $|\mathrm{Type}_T(u)| \leq \prod_{t=1}^d u_i^{-u_i T}$ .

*Proof.* We prove the inequality with a probabilistic argument. Consider all the possible sequences  $\boldsymbol{y}$  of length T generated i.i.d. from a distribution over d symbols equal to  $\boldsymbol{u} = [u_1, \dots, u_d]^{\top} \in \Delta^{d-1}$ . The sum of the probabilities of all these sequences is 1. Among all the sequences, there are the ones with type  $\boldsymbol{u}$ . Hence, for any  $\boldsymbol{u} \in Q$ , we have

$$1 \geq \sum_{\boldsymbol{y} \text{ has type } \boldsymbol{u}} \mathbb{P}\{N(1;\boldsymbol{y}) = u_1, \dots, N(d;\boldsymbol{y}) = u_d\} = \sum_{\boldsymbol{y} \text{ has type } \boldsymbol{u}} \prod_{i=1}^d u_i^{u_i T} = |\operatorname{Type}_T(\boldsymbol{u})| \prod_{i=1}^d u_i^{u_i T},$$

where the first equality is due the i.i.d. assumption and the second one is due to the fact that all the sequences of type u have the same probability.

# 13.4 Proof of Theorem 13.1

First of all, we need a couple of technical lemmas.

**Lemma 13.5.** Let  $a_1, ..., a_T > 0$  and  $b_1, ..., b_T > 0$ . Then, we have

$$\frac{\sum_{t=1}^{T} a_t}{\sum_{t=1}^{T} b_t} \le \max_{t=1,\dots,T} \frac{a_t}{b_t}.$$

*Proof.* Let  $j^* = \operatorname{argmax}_{t=1,\dots,T} \frac{a_t}{b_t}$ . Then, we have

$$\frac{\sum_{t=1}^{T} a_t}{\sum_{t=1}^{T} b_t} = \frac{a_{j^{\star}} \left(1 + \sum_{t \neq j^{\star}} \frac{a_t}{a_{j^{\star}}}\right)}{b_{j^{\star}} \left(1 + \sum_{t \neq j^{\star}} \frac{b_t}{b_{z^{\star}}}\right)} \le \frac{a_{j^{\star}}}{b_{j^{\star}}},$$

because  $\frac{a_{j\star}}{b_{j\star}} \geq \frac{a_t}{b_t}$  for all t, that implies  $\frac{a_t}{a_{j\star}} \leq \frac{b_t}{b_{j\star}}$ .

**Lemma 13.6.** Let  $T \ge 1$  and  $a_1, \ldots, a_T \in \{0, 1, \ldots, T\}$  such that  $\sum_{t=1}^T a_t = T$ . Then, the function  $f(a_1, \ldots, a_T) = \prod_{t=1}^T \frac{a_t^{a_t}}{\Gamma(a_t + \frac{1}{2})}$  is maximized when  $a_1 = T$  and  $a_2 = a_3 = \cdots = a_T = 0$ .

*Proof.* First, let's show that for  $a_r \ge a_s$ , we have  $f(a_1, \ldots, a_r, \ldots, a_s, \ldots, a_T)/f(a_1, \ldots, a_r+1, \ldots, a_s-1, \ldots, a_T) \le 1$ . This ratio is equal to  $\phi(a_r)/\phi(a_s-1)$ , where

$$\phi(x) := \frac{x^x}{\Gamma\left(x + \frac{1}{2}\right)} \frac{\Gamma\left(x + \frac{3}{2}\right)}{(x+1)^{x+1}} = \frac{x^x}{(x+1)^{x+1}} \left(x + \frac{1}{2}\right),$$

where we used  $\Gamma(x+1) = x\Gamma(x)$ . Given that for  $a_r = a_s - 1$  we have that  $\phi(a_r)/\phi(a_s - 1) = 1$ , we have to show that the  $\phi$  is decreasing. The derivative of  $\ln \phi(x)$  is

$$(\ln \phi)'(x) = \ln(x) - \ln(x+1) + \frac{1}{x+\frac{1}{2}} = -\int_{x}^{x+1} \frac{1}{y} \, \mathrm{d}y + \frac{1}{x+\frac{1}{2}} \le -\frac{1}{\int_{x}^{x+1} y \, \mathrm{d}y} + \frac{1}{x+\frac{1}{2}}$$
$$= -\frac{1}{x+\frac{1}{2}} + \frac{1}{x+\frac{1}{2}} = 0.$$

Repeatedly applying the fact that  $f(a_1,\ldots,a_r,\ldots,a_s,\ldots,a_T)/f(a_1,\ldots,a_r+1,\ldots,a_s-1,\ldots,a_T) \leq 1$  to couples of variables, gives the stated result.

The key lemma is the following one.

**Lemma 13.7.** For any fixed rebalanced portfolio u and any sequence of market gains  $w_t \in \mathbb{R}^d_{\geq 0}$  for t = 1, ..., T, a F-weighted portfolio guarantees

$$\frac{\operatorname{Wealth}_{T}(\boldsymbol{u})}{\operatorname{Wealth}_{T}} \leq \max_{\boldsymbol{j} \in \{1, \dots, d\}^{T}} \frac{\prod_{t=1}^{T} u_{j_{t}}}{\int \prod_{t=1}^{T} x_{j_{t}} dF(\boldsymbol{x})}.$$

Proof. Observe that

Wealth<sub>T</sub>(
$$\boldsymbol{u}$$
) =  $\prod_{t=1}^{T} \langle \boldsymbol{w}_t, \boldsymbol{u} \rangle = \prod_{t=1}^{T} \sum_{i=1}^{d} w_{t,i} u_i = \sum_{\boldsymbol{j} \in \{1, \dots, d\}^T} \prod_{t=1}^{T} u_{j_t} w_{t,j_t},$ 

where in the last equality we have expressed the products as sum over all the possible combinations of the terms in the sum. In the same way, using (13.3), we have

$$Wealth_T = \int_{\Delta^{d-1}} Wealth_T(\boldsymbol{x}) dF(\boldsymbol{x}) = \int_{\Delta^{d-1}} \prod_{t=1}^T \langle \boldsymbol{w}_t, \boldsymbol{x} \rangle dF(\boldsymbol{x}) = \sum_{\boldsymbol{i} \in \{1, \dots, d\}^T} \int_{\Delta^{d-1}} \prod_{t=1}^T x_{j_t} w_{t, j_t} dF(\boldsymbol{x}).$$

We now use Lemma 13.5, to obtain

$$\frac{\text{Wealth}_{T}(\boldsymbol{u})}{\text{Wealth}_{T}} = \frac{\sum_{\boldsymbol{j} \in \{1, \dots, d\}^{T}} \prod_{t=1}^{T} u_{j_{t}} w_{t, j_{t}}}{\sum_{\boldsymbol{j} \in \{1, \dots, d\}^{T}} \int_{\Delta^{d-1}} \prod_{t=1}^{T} x_{j_{t}} w_{t, j_{t}} \, dF(\boldsymbol{x})} = \frac{\sum_{\boldsymbol{j} \in \{1, \dots, d\}^{T}, \prod_{t=1}^{T} w_{t, j_{t}} > 0} \prod_{t=1}^{T} u_{j_{t}} w_{t, j_{t}}}{\sum_{\boldsymbol{j} \in \{1, \dots, d\}^{T}, \prod_{t=1}^{T} w_{t, j_{t}} > 0} \int_{\Delta^{d-1}} \prod_{t=1}^{T} x_{j_{t}} w_{t, j_{t}} \, dF(\boldsymbol{x})}$$

$$\leq \max_{\boldsymbol{j} \in \{1, \dots, d\}^{T}, \prod_{t=1}^{T} w_{t, j_{t}} > 0} \frac{\prod_{t=1}^{T} u_{j_{t}} w_{t, j_{t}}}{\int_{\Delta^{d-1}} \prod_{t=1}^{T} x_{j_{t}} w_{t, j_{t}} \, dF(\boldsymbol{x})}$$

$$= \max_{\boldsymbol{j} \in \{1, \dots, d\}^{T}, \prod_{t=1}^{T} w_{t, j_{t}} > 0} \frac{\prod_{t=1}^{T} u_{j_{t}}}{\int_{\Delta^{d-1}} \prod_{t=1}^{T} x_{j_{t}} \, dF(\boldsymbol{x})} \leq \max_{\boldsymbol{j} \in \{1, \dots, d\}^{T}, \prod_{t=1}^{T} w_{t, j_{t}} \, dF(\boldsymbol{x})} \frac{\prod_{t=1}^{T} u_{j_{t}}}{\int_{\Delta^{d-1}} \prod_{t=1}^{T} x_{j_{t}} \, dF(\boldsymbol{x})} . \qquad \square$$

This Lemma has a very easy and powerful interpretation: for a given  $\mathbf{j} \in \{1, \dots, d\}^T$ , we have that  $\prod_{t=1}^T u_{j_t}$  is nothing else that the wealth of the constantly rebalanced portfolio  $\mathbf{u}$  when the market gains for  $t=1,\dots,T$  are

$$\boldsymbol{w}_t = [0, \dots, 0, \underbrace{1}_{\text{position } j_t}, 0, \dots, 0] \in \mathbb{R}^d$$
.

Similarly for the wealth of the algorithm. This means that the Lemma shows that the worst case regret ratio is achieved for market gains where only one coordinate is 1 and all the others are zero, so-called Kelly market vectors or "horse race" vectors. So, this lemma allows us to simplify the analysis by completely removing the market gains from the upper bound. As such, the upper bound is worst-case with respect to the sequence of market gains. Yet, given that with our choices of F distributions the final regret is logarithmic, it also shows that the market gains can only have a limited influence on the regret of the algorithm.

We can now prove the regret guarantees for universal portfolio with two different distributions F.

*Proof of Theorem 13.1.* First, using Lemma 13.3, for any  $j \in \{1, ..., d\}^T$  and  $u \in \Delta^{d-1}$ , we have

$$\prod_{t=1}^T u_{j_t} = \prod_{i=1}^d u_i^{N(i;\boldsymbol{j})} \leq \prod_{i=1}^d \left(\frac{N(i;\boldsymbol{j})}{T}\right)^{N(i;\boldsymbol{j})},$$

where N(i; j) is  $\sum_{t=1}^{T} \mathbf{1}[j_t = i]$ .

Let's first consider the Dirichlet distribution. First, observe that it can be shown that  $\int_{\Delta^{d-1}} \prod_{t=1}^T x_{j_t} dF(x)$  has a closed form expression for the specific distribution we have selected:

$$\int_{\Delta^{d-1}} \prod_{t=1}^{T} x_{j_t} \mathrm{d}F(\boldsymbol{x}) = \frac{\pi^{-d/2} \Gamma\left(\frac{d}{2}\right)}{\Gamma\left(T + \frac{d}{2}\right)} \prod_{i=1}^{d} \Gamma\left(N(i; \boldsymbol{j}) + \frac{1}{2}\right) \ .$$

Putting everything together and using Lemmas 13.7 and 13.6, we have

$$\max_{j \in \{1, \dots, d\}^T} \frac{\prod_{t=1}^T u_{j_t}}{\int_{\Delta^{d-1}} \prod_{t=1}^T x_{j_t} dF(\boldsymbol{x})} \leq \max_{a_1, \dots, a_d \geq 0: \sum_{i=1}^d a_i = T} \pi^{d/2} \frac{\Gamma\left(T + \frac{d}{2}\right)}{\Gamma\left(\frac{d}{2}\right) T^T} \prod_{i=1}^d \frac{a_i^{a_i}}{\Gamma\left(a_i + \frac{1}{2}\right)} 
= \pi^{d/2} \frac{\Gamma\left(T + \frac{d}{2}\right)}{\Gamma\left(\frac{d}{2}\right) T^T} \frac{T}{\Gamma\left(T + \frac{1}{2}\right)} \frac{1}{\pi^{\frac{d-1}{2}}} = \frac{\sqrt{\pi}\Gamma\left(T + \frac{d}{2}\right)}{\Gamma\left(\frac{d}{2}\right) \Gamma\left(T + \frac{1}{2}\right)}.$$

Analogously, when F is the uniform distribution, it can be shown that

$$\int_{\Delta^{d-1}} \prod_{t=1}^{T} x_{j_t} \, \mathrm{d}F(\boldsymbol{x}) = \frac{1}{\binom{T+d-1}{d-1} |\operatorname{Type}_T(N(1;\boldsymbol{j})/T,\dots,N(d;\boldsymbol{j})/T)|},$$

where  $|\operatorname{Type}_T(a_1,\ldots,a_d)|$  is the number of sequences of type  $(a_1,\ldots,a_d)$ . From Theorem 13.4, we have that  $|\operatorname{Type}_T(N(1;\boldsymbol{j})/T,\ldots,N(d;\boldsymbol{j})/T)| \leq \prod_{i=1}^d \left(\frac{N(i;\boldsymbol{j})}{T}\right)^{-N(i;\boldsymbol{j})}$ . Hence, when F is the uniform distribution, we have

$$\max_{\boldsymbol{j} \in \{1, \dots, m\}^T} \frac{\prod_{t=1}^T u_{j_t}}{\int_{\Delta^{d-1}} \prod_{t=1}^T x_{j_t} \, \mathrm{d}F(\boldsymbol{x})} \leq \binom{T+d-1}{d-1} \ .$$

The second inequality is obtained using the inequality  $\binom{n}{k} \leq \left(\frac{en}{k}\right)^k$ .

# 13.5 Portfolio Selection through Online-Newton-Step

While the F-weighted portfolio algorithm can have optimal regret, its computational complexity is very high, both in T and d. In fact, we have to calculate an integral over d dimensions in each step. While it is possible to have a closed form update with complexity  $\mathcal{O}(t)$  [Cover and Ordentlich, 1996], it is also natural to look for alternatives with a lower computational complexity.

One might be tempted to use any other OCO algorithm to solve the portfolio selection problem. However, as we have seen in Section 13.1, the gradients in general can be unbounded. Hence, we again consider an easier setting: We assume that the market gains are both lower bounded by c>0 and upper bounded by  $C<\infty$ . We stress that Theorem 13.1 does not require this assumption, but we use it to derive a simpler algorithm, still with a logarithmic regret.

Now, we might be tempted to think that the losses are strongly convex, because Theorem 13.1 shows a logarithmic regret. This is clearly false: The Hessian of each function has rank 1 and unfortunately in the worst case the sum of T losses can also have a singular Hessian. Even assuming the Hessian of the sum of the losses is not singular, we would need its minimal eigenvalue to grow over time. Again, this does not happen in a worst-case scenario. Hence, we need another way.

Observe that the losses in portfolio selection are 1-exp-concave. In fact,  $\exp(-\ell_t(\boldsymbol{x})) = \langle \boldsymbol{w}_t, \boldsymbol{x} \rangle$  that is concave. Hence, if the gradients and the domain are bounded, we can apply the Online-Newton-Step algorithm. In particular, following Example 7.31, we need to find  $\beta \leq \frac{1}{2}$  such that  $|\beta\langle\nabla\ell_t(\boldsymbol{x}),\boldsymbol{x}-\boldsymbol{u}\rangle| \leq \frac{1}{2}$  for any  $\boldsymbol{x},\boldsymbol{u}\in\Delta^{d-1}$ . For the gradient, we have  $\nabla\ell_t(\boldsymbol{x}) = \frac{\boldsymbol{w}_t}{\langle \boldsymbol{w}_t,\boldsymbol{x}\rangle}$ , hence  $\|\nabla\ell_t(\boldsymbol{x})\|_{\infty} \leq \frac{C}{c}$ . Moreover,  $\|\boldsymbol{x}-\boldsymbol{u}\|_1 \leq 2$  for any  $\boldsymbol{x},\boldsymbol{u}\in\Delta^{d-1}$ . Hence, we can set  $\beta = \frac{c}{4C}$ .

The resulting algorithm is the following one.

#### Algorithm 13.2 Online Newton Step for Portfolio Selection

```
Require: \lambda > 0, C < \infty, c > 0

1: Set \beta = \frac{c}{4C}

2: for t = 1 to T do

3: Set x_t = \operatorname{argmin}_{\boldsymbol{x} \in \Delta^{d-1}} \sum_{i=1}^{t-1} \langle \boldsymbol{g}_i, \boldsymbol{x} \rangle + \frac{\lambda}{2} \|\boldsymbol{x}\|_2^2 + \frac{\beta}{2} \sum_{i=1}^{t-1} (\langle \boldsymbol{g}_i, \boldsymbol{x} - \boldsymbol{x}_i \rangle)^2

4: Pay \ell_t(\boldsymbol{x}_t) for \ell_t(\boldsymbol{x}) = -\ln \langle \boldsymbol{w}_t, \boldsymbol{x} \rangle

5: Set \boldsymbol{g}_t = -\frac{\boldsymbol{w}_t}{\langle \boldsymbol{w}_t, \boldsymbol{x}_t \rangle}

6: end for
```

As shown in Exercise 7.12, the update can also be divided in two steps: first minimizing over the entire space and then a Bregman projection.

As we have seen in Section 7.10, the regret upper bound of the Online-Newton-Step for any  $u \in \Delta^{d-1}$  is

$$\operatorname{Regret}_T = \operatorname{ln} \operatorname{Wealth}_T(\boldsymbol{u}) - \operatorname{ln} \operatorname{Wealth}_T = \sum_{t=1}^T \ln \langle \boldsymbol{w}_t, \boldsymbol{u} \rangle - \sum_{t=1}^T \ln \langle \boldsymbol{w}_t, \boldsymbol{x}_t \rangle \leq \frac{\lambda}{2} \|\boldsymbol{u}\|_2^2 + \frac{d}{2\beta} \ln \left(1 + \frac{\beta T L^2}{d\lambda}\right),$$

where  $\|\nabla \ell_t(\boldsymbol{x}_t)\|_2 \leq L$ . In our setting, this becomes

$$\operatorname{Regret}_T = \operatorname{ln} \operatorname{Wealth}_T(\boldsymbol{u}) - \operatorname{ln} \operatorname{Wealth}_T = \sum_{t=1}^T \ln \langle \boldsymbol{w}_t, \boldsymbol{u} \rangle - \sum_{t=1}^T \ln \langle \boldsymbol{w}_t, \boldsymbol{x}_t \rangle \leq \frac{\lambda}{2} + \frac{2dC}{c} \ln \left( 1 + \frac{CT}{4c\lambda} \right),$$

where we used the fact that  $\|\nabla \ell_t(\boldsymbol{x}_t)\|_2 \leq \frac{\sqrt{d}C}{c}$ .

#### 13.6 Application: Portfolio Selection and Continuous Coin-Betting

Consider the coin-betting online problem. We said that it corresponds to  $\mathcal{V} = [-1, 1]$  and  $\ell_t(x) = \ln(1 + c_t x)$ , where the coin outcome  $c_t \in \{-1, 1\}$ . We also considered an extension of this problem, the *continuous coin* betting problem, where  $c_t \in [-1, 1]$ . Now, we show how to reduce the continuous coin-betting problem to portfolio selection.

The reduction is straightforward: We consider portfolio selection with 2 stocks, and we set the market gains to  $w_{t,1}=1+c_t$  and  $w_{t,2}=1-c_t$ . Note that  $w_{t,1},w_{t,2}\geq 0$ , so they are legal market gains. Define  $[x_t,1-x_t]$  the play of a 2-stocks portfolio algorithm, where  $0\leq x_t\leq 1$ . Then, taking

$$\beta_t = 2x_t - 1$$

as the signed betting fraction a continuous-coin-betting algorithm on  $c_t$  ensures that the gain in the coin betting problem coincides with the gain in the portfolio selection problem.

The proof is immediate. We have

$$w_{t,1}x_t + w_{t,2}(1-x_t) = x_t + x_tc_t + (1-c_t)(1-x_t) = x_t + x_tc_t + 1 - x_t - c_t + c_tx_t = 1 + c_t\beta_t$$

where  $\beta_t$  is the signed betting fraction equal to  $2x_t - 1$ . Given that  $x_t \in [0, 1]$ , the range of the betting fractions is in [-1, 1] as we wanted.

This implies that we can use the above reduction to transform any portfolio algorithm with 2 stocks into an algorithm for continuous coin betting. In turn, this means that portfolio algorithms with 2 stocks can be used for online convex optimization, see Chapter 10. This does not make the continuous coin-betting algorithm superfluous because the update rule of universal portfolio algorithm even with 2 stocks is still linear in the iteration number.

# 13.7 Application: From Portfolio Regret to Time-Uniform Concentration Inequalities

In this section, we will show another application of portfolio algorithms: The regret guarantee of portfolio algorithms can be used to derive time-uniform concentration inequalities.

Consider a sequence of random variables  $Z_1, Z_2, \ldots$  and assume that  $E[Z_t|Z_1, \ldots, Z_{t-1}] = \mu$  for all t. Also, assume that  $Z_t$  has values on [0,1]. We want to estimate  $\mu$ , giving confidence intervals  $[l_t, u_t]$  that are valid for any t with probability at least  $1-\delta$ , that is,  $\mathbb{P}\{\forall t, \mu \notin [l_t, u_t]\} \leq \delta$ . The classic approach is to estimate  $\mu$  with  $\hat{\mu}_t = \frac{1}{t} \sum_{i=1}^t Z_i$ , then invoke a concentration inequality that holds uniformly over time to obtain the confidence intervals. However, for most of the well-known concentration inequalities, we would have *vacuous* confidence intervals when t is small, in the sense that  $u_t - l_t > 1$  for all t smaller than some constant.

Here, we will show how a portfolio algorithm immediately gives rise to non-vacuous time-uniform confidence intervals, even with a single sample!

The idea is the following: We will construct a continuous coin-betting game on a fair coin from the problem of estimating the unknown mean. Then, we will use the following theorem that says that the probability to make a large amount of money at any moment in time is small.

**Theorem 13.8** (Ville's inequality). Let  $Y_0, Y_1, \ldots, a$  non-negative supermartingale and  $\delta \in (0, 1]$ . Then, we have

$$\mathbb{P}\left\{\max_{t} Y_{t} \geq \frac{1}{\delta}\right\} \leq \mathbb{E}[Y_{0}]\delta.$$

Warm-up: From KT to a concentration inequality As a warm-up example, consider the KT algorithm that bets  $\beta_t$  Wealth $_{t-1}$  in round t on the outcome of the continuous coin  $c_t = Z_t - \mu$ . We have that the wealth of the algorithm is a martingale and hence a supermartingale. As in Example 3.7, we have

$$\mathbb{E}[\text{Wealth}_t \mid \text{Wealth}_{t-1}] = \text{Wealth}_{t-1} \, \mathbb{E}[1 + \beta_t c_t \mid \text{Wealth}_{t-1}]$$

$$= \text{Wealth}_{t-1} \, \mathbb{E}[1 + \beta_t (Z_t - \mu) \mid \text{Wealth}_{t-1}] = \text{Wealth}_{t-1} \, .$$

Moreover, the wealth is non-negative because KT guarantees a non-negative wealth on any sequence of coins. So, starting with \$1, using Ville's inequality and Theorem 10.5, we obtain

$$\delta \geq \mathbb{P}\left\{\max_{t} \operatorname{Wealth}_{t} \geq \frac{1}{\delta}\right\} = \mathbb{P}\left\{\max_{t} \ln \operatorname{Wealth}_{t} \geq \ln \frac{1}{\delta}\right\} \geq \mathbb{P}\left\{\max_{t} \frac{\left(\sum_{i=1}^{t} c_{t}\right)^{2}}{4t} - \frac{1}{2}\ln(Kt) \geq \ln \frac{1}{\delta}\right\},$$

where K is a universal constant. An equivalent statement is to say that with probability at least  $1-\delta$  we have uniformly over t that

$$\left| \frac{1}{t} \sum_{i=1}^{t} Z_i - \mu \right| = \frac{1}{t} \left| \sum_{i=1}^{t} c_i \right| \le \frac{2\sqrt{\ln \frac{\sqrt{Kt}}{\delta}}}{t} .$$

Observe that  $Y_t = \sum_{i=1}^t (Z_i - \mu)$  is a martingale, so let's compare this concentration to Hoeffding-Azuma inequality in Theorem 3.8. We almost get the same thing, but here we have an additional  $\ln \sqrt{T}$  term. However, this concentration is uniform over time, that justifies the additional term in the logarithm. To summarize, the regret/reward guarantee of KT implies a concentration inequality.

From Universal Portfolio to a concentration inequality Let's now improve this reasoning using a universal portfolio algorithm to bet on the same outcomes. Similarly to Section 13.6, we will transform the random variables  $Z_t$  to a sequence of two market gains. Set  $w_{t,1} = 1 + \frac{Z_t - \mu}{\mu}$  and  $w_{t,2} = 1 - \frac{Z_t - \mu}{1 - \mu}$ . Given that  $Z_t - \mu \in [-\mu, 1 - \mu]$ , we have that  $w_{t,1}$  and  $w_{t,2}$  are non-negative. Moreover, as before we still have that the wealth will be a martingale. So, we have

$$\max_{\boldsymbol{u} \in \Delta} \sum_{i=1}^{t} \ln \langle \boldsymbol{w}_i, \boldsymbol{u} \rangle = \max_{\beta \in [-\frac{1}{1-\mu}, \frac{1}{\mu}]} \sum_{i=1}^{t} \ln \left( 1 + (Z_i - \mu)\beta \right) .$$

Reasoning as above, we have

$$\mathbb{P}\left\{\max_{t} \max_{\beta \in [-\frac{1}{1-\mu}, \frac{1}{\mu}]} \sum_{i=1}^{t} \ln\left(1 + (Z_i - \mu)\beta\right) - \operatorname{Regret}_t \ge \ln\frac{1}{\delta}\right\} \le \delta,$$

where  $\operatorname{Regret}_t$  is the regret of the portfolio algorithm with 2 stocks. If we use a portfolio algorithm with logarithmic regret, given that  $[-1,1] \subset [-\frac{1}{1-\mu},\frac{1}{\mu}]$ , this expression gives always a bigger wealth than the KT strategy we have just seen. In turn, a bigger wealth corresponds to a tighter concentration.

Let's be more precise instantiating the above idea with a F-weighted portfolio algorithm, with F equal to the Dirichlet(1/2,1/2) distribution.

**Theorem 13.9.** Let  $\delta \in (0,1)$ . Assume  $Z_1, Z_2, \ldots$  a sequence of random variables such that for each i we have  $0 \le Z_i \le 1$  and  $\mathbb{E}[Z_i|Z_1,\ldots,Z_{i-1}] = \mu$  almost surely. Let  $G_t(\beta,\mu) := \sum_{i=1}^t \ln{(1+\beta(Z_i-\mu))}, \ R_t := \ln{\frac{\sqrt{\pi}\Gamma(t+1)}{\Gamma(t+\frac{1}{2})}},$  and

$$S_t := \left\{ m \in [0, 1] : \max_{\beta \in [-\frac{1}{1-m}, \frac{1}{m}]} G_t(\beta, m) - R_t \le \ln \frac{1}{\delta} \right\}.$$

Then, with probability at least  $1 - \delta$  and uniformly over t, after observing t random variables we have  $\mu \in \cap_{i=1}^t \mathcal{S}_i$ . Moreover, we have that  $\mathcal{S}_t$  is an interval  $[l_t, u_t] \subseteq [0, 1]$  for all t = 1, ..., T.

*Proof.* Following the reasoning above and the fact that the regret of the F-weighted portfolio algorithm with 2 stocks and F = Dirichlet(1/2, 1/2) is upper bounded by  $R_t$  using Theorem 13.1, we get that  $\mu \in \mathcal{S}_t$ . From the fact that this holds with probability  $1 - \delta$  uniformly over time, we get that at time  $t \mu$  must be in the intersection of the sets  $\mathcal{S}_1, \ldots, \mathcal{S}_t$ .

For the second claim, first denote by  $\beta^*(m) := \operatorname{argmax}_{\beta \in [-\frac{1}{1-m}, \frac{1}{m}]} G_t(\beta, m)$  and  $\hat{G}_t(m) = \operatorname{max}_{\beta \in [-\frac{1}{1-\mu}, \frac{1}{\mu}]} G_t(\beta, m)$ . Observe that the derivative of  $G_t$  with respect to its first argument is

$$G'_t(\beta, m) = \sum_{i=1}^t \frac{Z_i - m}{1 + \beta(Z_i - m)}$$
.

So, we have that  $G'_t(0, \hat{\mu}_t) = 0$ . Given that  $G_t(\beta, m)$  is concave in  $\beta$ , then  $G_t(\beta, \hat{\mu}_t)$  has a maximum with respect to the first argument in  $\beta = 0$  and the value of the function is 0.

For  $m' > \hat{\mu}_t$ ,  $G'_t(0, m') < 0$ . Since  $G_t(\beta, m')$  is concave in  $\beta$ , we have  $\beta^*(m') < 0$ . In the same way, for  $m' < \hat{\mu}_t$  we have  $\beta^*(m') > 0$ .

Now, let us start with  $m' > \hat{\mu}_t$  and prove that  $\hat{G}_t(m)$  is nondecreasing, the other side is analogous. Consider  $m_1 > m_2 > \hat{\mu}_t$ . Given that  $\beta^*(m_2) < 0$ , we have

$$\hat{G}_t(m_2) = G_t(\beta^*(m_2), m_2) \le G_t(\beta^*(m_2), m_1) \le G_t(\beta^*(m_1), m_1) = \hat{G}_t(m_1),$$

where the first inequality is due to the fact that  $G_t(\beta,m)$  is nondecreasing in m when  $\beta<0$  and the second inequality is due to the fact that the negative part of the interval  $[-\frac{1}{1-m_1},\frac{1}{m_1}]$  contains the negative part of the interval  $[-\frac{1}{1-m_2},\frac{1}{m_2}]$  and we know the maximum  $\beta$  is negative. Hence,  $\hat{G}_t(m)$  is a quasi-convex function of m and hence  $\mathcal{S}_t$  is an interval.

**Remark 13.10.** Given that  $S_t$  is an interval, we can find  $S_t = [l_t, u_t]$  efficiently using the bisection algorithm.

Now, we gather some more intuition on the inequality of Theorem 13.9.

It may not seem obvious if the maximum log wealth is a better candidate for constructing a confidence sequence than the standard ones like Bernoulli KL-divergence based bound [e.g., Garivier and Cappé, 2011, Theorem 10], which works for random variables supported in [0,1]:

$$\mathbb{P}\left\{\max_{t} t \cdot \mathrm{KL}(\hat{\mu}_{t}, \mu) - \ln f(t) \ge \ln \frac{1}{\delta}\right\} \le \delta,$$

where  $\hat{\mu}_t = \frac{1}{t} \sum_{i=1}^t Z_i$ ,  $\mathrm{KL}(p,q) := p \ln \frac{p}{q} + (1-p) \ln \frac{1-p}{1-q}$ , and f(t) grows polynomially in t or slower. So, in the following proposition we show that the maximum log wealth is never worse than the KL divergence, which supports a viewpoint that the KL divergence is a special case of the maximum log wealth and that confidence bounds constructed with the maximum wealth are never worse than those with KL divergence, ignoring the minor difference in  $\ln f(t)$ .

**Proposition 13.11.** Let  $Z_1, ..., Z_t \in [0, 1]$ ,  $\hat{\mu}_t = \frac{1}{t} \sum_{i=1}^t Z_i$ , and  $\mu \in [0, 1]$ . Then,

$$\max_{\beta \in \left[-\frac{1}{1-\mu}, \frac{1}{\mu}\right]} \sum_{i=1}^{t} \ln\left(1 + \beta(Z_i - \mu)\right) \ge t \cdot KL\left(\hat{\mu}_t, \mu\right),$$

where we achieve the equality if  $X_1, \ldots, X_t \in \{0, 1\}$  almost surely.

*Proof.* Using Jensen's inequality, we have for any  $Z \in [0,1]$  that

$$\ln(1 + \beta(Z - \mu)) = \ln[Z(1 + \beta(1 - \mu)) + (1 - Z)(1 + \beta(0 - \mu))]$$
  
 
$$\geq Z \ln(1 + \beta(1 - \mu)) + (1 - Z) \ln(1 + \beta(0 - \mu)),$$

Note that we achieve equality when Z = 1 or Z = 0. Then, we have

$$\max_{\beta \in [-\frac{1}{1-\mu}, \frac{1}{\mu}]} \sum_{i=1}^{t} \ln(1 + \beta(Z_i - \mu)) \ge \max_{\beta \in [-\frac{1}{1-\mu}, \frac{1}{\mu}]} \sum_{i} Z_i \ln(1 + \beta(1-\mu)) + (1 - Z_i) \ln(1 - \beta\mu)$$

$$= \max_{\beta \in [-\frac{1}{1-\mu}, \frac{1}{\mu}]} t[\hat{\mu}_t \ln(1 + \beta(1-\mu)) + (1 - \hat{\mu}_t) \ln(1 - \beta\mu)].$$

As the right hand side is concave in  $\beta$ , it remains to maximize the right hand side over  $\beta$ . The solution is  $\beta = \frac{\hat{\mu}_t - \mu}{\mu(1-\mu)}$  with which the maximum becomes  $t \cdot \text{KL}(\hat{\mu}_t, \mu)$ .

Second, we show that the confidence intervals obtained by the numerical inversion of Theorem 13.9 are *never* vacuous

**Theorem 13.12.** Under the assumptions of Theorem 13.9, for any t we have that  $u_t - \ell_t \le u_1 - \ell_1 = 1 - \frac{\delta}{2}$ .

*Proof.* First of all, it should be clear that the width of the confidence intervals  $u_t - \ell_t$  are always smaller than the one calculated with 1 sample,  $u_1 - \ell_1$ . With only one sample, the upper and lower bound have a closed formula. Indeed, the argmax of  $G_t(\beta, m)$  with respect to  $\beta$  over  $[-\frac{1}{1-m}, \frac{1}{m}]$  is achieved in  $\beta = \frac{1}{m}$  if  $Z_1 - m > 0$  and in  $\beta = -\frac{1}{1-m}$  for  $Z_1 - m < 0$ . This implies that

$$\ell_1 = \frac{Z_1}{\exp(R_1 + \ln\frac{1}{\delta})} \qquad \qquad \text{and} \qquad \qquad u_1 = 1 - \frac{1 - Z_1}{\exp(R_1 + \ln\frac{1}{\delta})} \;.$$

Given that  $R_1 = \ln 2$ , subtracting the upper bound from the lower bound we get the stated bound for any  $Z_1$ .

Finally, besides implying the KL bound above, the implicit concentration in Theorem 13.9 also implies an empirical Bernstein time-uniform concentration. It is worth stressing that the numerically evaluated interval  $[l_t, u_t]$  is strictly smaller than the upper bound in the following theorem, given that Theorem 13.12 tells us that the width of numerically calculated intervals are always strictly smaller than 1.

**Theorem 13.13.** Under the assumptions of Theorem 13.9, denote by  $\hat{\mu}_i = \frac{1}{i} \sum_{j=1}^i Z_j$ ,  $V_i = \sum_{j=1}^i (Z_j - \hat{\mu}_i)^2$ ,  $\hat{R}_i = \ln \frac{\sqrt{\pi}\Gamma(i+1)}{\delta\Gamma(i+\frac{1}{2})}$ , and

$$\epsilon_i = \frac{(4/3)i\hat{R}_i + \sqrt{16/9i^2\hat{R}_i^2 + 8V_i\hat{R}_i(i^2 - 2i\hat{R}_i)}}{2i^2 - 4i\hat{R}_i} \ .$$

Then, with probability at least  $1 - \delta$  uniformly for all t such that  $t > 2\hat{R}_t$ , we have

$$\max_{i=1,\dots,t} \hat{\mu}_i - \epsilon_i \le \mu \le \min_{i=1,\dots,t} \hat{\mu}_i + \epsilon_i.$$

For t big enough the deviation is roughly  $\frac{(4/3)\ln(\sqrt{t}/\delta)}{t} + \frac{\sqrt{2V_t\ln(\sqrt{t}/\delta)}}{t}$ , similarly to the inequalities first proposed in Audibert et al. [2009], Maurer and Pontil [2009].

**Remark 13.14.** One can easily see that, in terms of the scaling with  $\ln(1/\delta)$ , the factor  $\sqrt{2(\frac{1}{t}V_t)/t}$  is the optimal one due to the central limit theorem. For the scaling with t, by changing the weight distribution F it is also possible to obtain  $\sqrt{\frac{2(\frac{1}{t}V_t)\ln(\ln(V_t))+o(\ln\ln t)}{t}}$  as  $t\to\infty$ , which matches the law of the iterated logarithm (thus asymptotically optimal), see Orabona and Jun [2024].

We can see the performance of this approach compared to a state-of-the-art closed form concentration in Figures 13.1-13.4. We repeat each experiment 10 times and use the first 5 in which all the algorithms do not fail. In fact, all the algorithms/inequalities will fail with probability  $\delta$  and averaging over their failing runs would result in confidence sequences with smaller widths. We set  $\delta = 0.05$  in all the experiments.

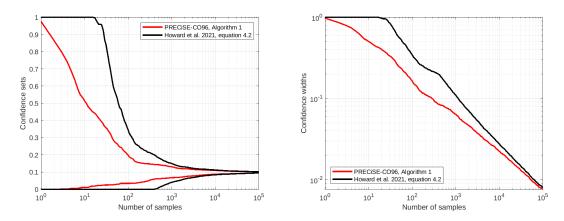

Figure 13.1: Confidence intervals for Theorem 13.9 and Howard et al. [2021] for a sequence of random variables drawn i.i.d. from Bernoulli(0.1).

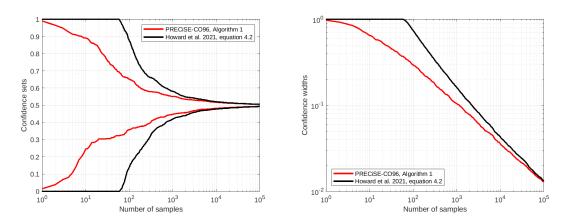

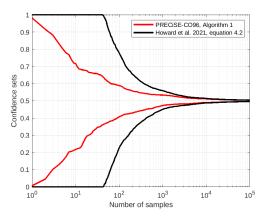

Figure 13.2: Confidence intervals for Theorem 13.9 and Howard et al. [2021] for a sequence of random variables drawn i.i.d. from Bernoulli(0.5).

To prove this theorem, we first need a technical lemma.

**Lemma 13.15.** Let  $f(x) = ax + b(\ln(1-|x|) + |x|)$ , where  $a \in \mathbb{R}$  and  $b \ge 0$ . Then,  $\operatorname{argmax}_{x \in [-1,1]} f(x) = \frac{a}{|a|+b}$  and  $\max_{x \in [-1,1]} f(x) = b\psi(\frac{a}{b}) \ge \frac{a^2}{(4/3)|a|+2b}$ , where  $\psi(x) = |x| - \ln(|x|+1)$ .

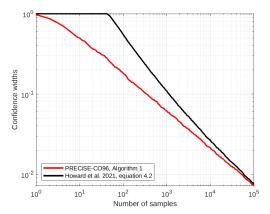

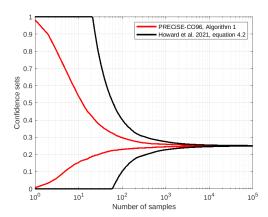

Figure 13.3: Confidence intervals for Theorem 13.9 and Howard et al. [2021] for a sequence of random variables drawn i.i.d. from Beta(1,1).

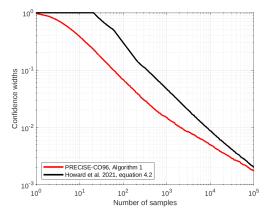

Figure 13.4: Confidence intervals for Theorem 13.9 and Howard et al. [2021] for a sequence of random variables drawn i.i.d. from Beta(10,30).

*Proof.* If b = 0, we have that argmax is sign(a). If a = 0, the argmax is 0. Hence, in the following, we can assume a and b to be different than 0.

We can rewrite the maximization problem as

$$\underset{x}{\operatorname{argmax}} f(x) = b \underset{x}{\operatorname{argmax}} \frac{a}{b} x + \ln(1 - |x|) + |x|.$$

From the optimality condition, we have that  $\frac{a}{b} - \frac{\operatorname{sign}(x^\star)}{1 - |x^\star|} + \operatorname{sign}(x^\star) = 0$ , that implies  $x^\star = \frac{a}{|a| + b}$ . Substituting this expression in f, we obtain the stated expression. The inequality is obtained by the elementary inequality  $\ln(1+x) \le x \cdot \frac{6+x}{6+4x}$  for  $x \ge 0$ .

We can now prove Theorem 13.13.

*Proof of Theorem 13.13.* For a given t, set  $\epsilon_t$  equal to  $\mu - \hat{\mu}_t$ , so that  $\epsilon + \hat{\mu}_t \in [0, 1]$ .

Consider the function  $f(a) = \frac{\ln(1+a)-a}{a^2/2}$  for a > -1. Set  $|x| \le 1$  and  $|\beta| < 1$ , so we have  $\beta x \ge -|\beta| > -1$ . From the sign of the first derivative, we have that f(a) is increasing. Hence, we have

$$\ln(1+\beta x) = \beta x + \frac{1}{2}(\beta x)^2 f(\beta x) \ge \beta x + \frac{1}{2}(\beta x)^2 f(-|\beta|) = \beta x + x^2 (|\beta| + \ln(1-|\beta|)).$$

Hence, for any  $\beta \in (-1, 1)$ , we have

$$\sum_{i=1}^{t} \ln(1 + \beta(Z_i - \mu)) = \sum_{i=1}^{t} \ln(1 + \beta(Z_i - \hat{\mu}_t - \epsilon_t))$$

$$\geq \beta \sum_{i=1}^{t} (Z_i - \hat{\mu}_t - \epsilon_t) + (\ln(1 - |\beta|) + |\beta|) \left( \sum_{i=1}^{t} (Z_i - \hat{\mu}_t)^2 + \epsilon_t^2 t - 2\epsilon_t \sum_{i=1}^{t} (Z_i - \hat{\mu}_t) \right)$$

$$= -\epsilon_t \beta t + (\ln(1 - |\beta|) + |\beta|) \left( \sum_{i=1}^{t} (Z_i - \hat{\mu}_t)^2 + \epsilon_t^2 t \right).$$

Hence, we have

$$\max_{\beta \in [-1,1]} \sum_{i=1}^{t} \ln(1 + \beta(Z_i - \hat{\mu}_t - \epsilon_t)) = \left(\sum_{i=1}^{t} (Z_i - \hat{\mu}_t)^2 + \epsilon_t^2 t\right) \psi\left(\frac{|\epsilon_t|t}{\sum_{i=1}^{t} (Z_i - \hat{\mu}_t)^2 + \epsilon_t^2 t}\right),$$

where  $\psi(x) = |x| - \ln(|x| + 1)$  and the equality is due to Lemma 13.15. From the inequality in Lemma 13.15 we also obtain

$$\max_{\beta \in [-1,1]} \sum_{i=1}^{t} \ln(1 + \beta(Z_i - \hat{\mu}_t - \epsilon_t)) \ge \frac{\epsilon_t^2 t^2}{(4/3)|\epsilon_t|t + 2\sum_{i=1}^{t} (Z_i - \hat{\mu}_t)^2 + 2\epsilon_t^2 t}.$$

Now, note that for any  $\mu \in [0,1]$  the interval  $[-\frac{1}{1-\mu},\frac{1}{\mu}]$  is contained in [-1,1]. Hence, from Theorem 13.9, uniformly on all t with probability at least  $1-\delta$ , we have

$$\frac{\epsilon_t^2 t^2}{(4/3)|\epsilon_t|t + 2\sum_{i=1}^t (Z_i - \hat{\mu}_t)^2 + 2\epsilon_t^2 t} \le R_t + \ln \frac{1}{\delta} = \hat{R}_t .$$

Assuming  $\epsilon_t$  positive and solving for it, we have the stated upper bound. By the symmetry of the formula, the expression for negative  $\epsilon_t$  has the opposite sign.

#### 13.8 History Bits

The distributional approach to betting and gambling was pioneered by Kelly [1956]. This approach assumes that the market gains are i.i.d. from a (known) distribution. Cover and Ordentlich [1996] proposed the first portfolio algorithm with a minimax regret, without assumptions over the market gains, improving over the result in Cover [1991]. The proof presented here follows the one in Cover and Ordentlich [1996], while Lemma 13.3 and Theorem 13.4 are adapted from the proofs of Cover and Thomas [2006, Theorem 11.1.2 and Theorem 11.1.3], respectively. Vovk and Watkins [1998] proved that *F*-weighted portfolio algorithms are instantiations of the Aggregating Algorithm [Vovk, 1990].

The use of EG for portfolio selection was proposed by Helmbold et al. [1998]. Stochastic approximations to the *F*-weighted portfolio update were proposed by Blum and Kalai [1997, 1999], Kalai and Vempala [2002]. Blum and Kalai [1997, 1999] also present a simpler proof for the uniform distribution case. The use of the Online Newton Step for portfolio selection was proposed by Hazan et al. [2006, 2007]. There is also a line of research that aims at designing algorithms on the efficiency-regret Pareto frontier [see, e.g., Tsai et al., 2023, and references therein].

The reduction in Section 13.6 is folklore, and it appears in Orabona and Jun [2024].

The results and proofs from Section 13.6 are taken from Orabona and Jun [2024]. Note that the computational complexity to calculate  $S_t$  in Theorem 13.9 is  $O(t^2)$ . Looser confidence intervals from portfolio algorithms but with complexity O(t) have been proposed in Orabona and Jun [2024] and Ryu and Bhatt [2022].

Ville's inequality is proved in Ville [1939, Page 84], where its meaning is exactly associated to betting. In fact, Ville [1939] also introduced the concept of martingale as the wealth of a betting strategy on a fair coin. The ideas of Ville were later used to design ideal tests for randomness of infinite sequences [Schnorr, 1971, Levin, 1976, Gács, 2005], "ideal" because none of these tests is computable.

There are two papers that at the same time and independently explicitly link hypothesis testing on a finite sequence of outcomes to betting. One is Cover [1974, Example 3], where an optimal betting strategy is defined in terms of the null hypothesis. The other one is Robbins and Siegmund [1974] that constructs confidence sequences from novel betting schemes and explicitly recognizes the connection between the sequential probability ratio test [Wald, 1945]. Very surprisingly, Robbins and Siegmund [1974, Section 9] seem to have proposed and analyzed the famous strategy of Krichevsky and Trofimov [1981] 7 years before them. However, while in the information theory literature these ideas flourished and gave birth to results on coding, compression, minimum description length, and gambling, they seem to disappear from the statistics community for 30 years. In this view, it is remarkable that Cover [1974] was submitted to Annals of Statistics and probably rejected, as it can be inferred from the footnote on its first page.

In fact, in the statistics literature gambling strategies reappear again only in the '90-'00s thanks to the book and papers by Shafer and Vovk. In particular, Vovk [1993], Shafer and Vovk [2001] aimed to found probabilities on a gametheoretic ground through betting schemes. However, the foundational approach in Shafer and Vovk [2001] also means that all the betting strategies they propose do not have closed form expressions and they cannot be easily implemented. Moreover, Shafer and Vovk [2001] does not contain any explicit concentration inequality, while the first concentration for game-theoretic probability derived by a betting scheme is in Vovk [2007], that derives a game-theoretic Hoeffding's inequality.

The first paper to consider an implementable strategy for testing through betting is by Hendriks [2018]. Directly building on Shafer and Vovk [2001] and Shafer et al. [2011], Hendriks [2018] proposes to construct testing martingales and confidence sequences for bounded random variables as uniform mixtures of constant betting strategies, effectively a F-weighted portfolio with the uniform distribution. Hendriks [2018] also showed empirically the good performance of the proposed approach in a simple statistical test. Waudby-Smith and Ramdas [2021] seem to follow the same approach as Hendriks [2018] but propose a number of heuristic betting algorithms to maximize the wealth as well as a discrete version of the uniform mixture that appeared in Hendriks [2018]. The idea of using the regret of gambling algorithms to prove concentration inequalities appear for the first time in Jun and Orabona [2019]. In particular, Jun and Orabona [2019] show how to easily derive a Law of Iterated Logarithm for sub-Gaussian random vectors in Banach spaces from the regret of a one-dimensional betting algorithm and the direction/magnitude reduction (see Section 10.4). In turn, their work was based on the seminal work in Rakhlin and Sridharan [2017] that showed an equivalence between the regret guarantee of online learning algorithms with linear losses and concentration inequalities. However, the proof technique in Jun and Orabona [2019] is different from the one in Rakhlin and Sridharan [2017] and it is specific to online algorithms that guarantee a non-negative exponential wealth for biased inputs. In particular, it allows to derive time-uniform concentrations, like the law of the iterated logarithm, that are not possible with the method in Rakhlin and Sridharan [2017]. More recently, Jang et al. [2023] showed how to derive tighter PAC-Bayes bounds from the regret of portfolio algorithms.

#### 13.9 Exercises

**Problem 13.1.** Assume that the market gains  $w_{t,i}$  are bounded in [c, C]. Find a variant of EG can does not need to know c and C and it achieves up to constants the same guarantee in (13.2).

## **Chapter 14**

# Dynamic, Strongly Adaptive, and Tracking Regret

In this chapter, we will see how to extend the notion of regret to a sequence of comparators instead of a single one. We saw that the definition of regret makes sense as a direct generalization of both the stochastic setting and the offline optimization. However, in some cases we want to guarantee something stronger, that is, we would like the algorithm to have small regret with respect to multiple comparators. There are multiple ways to formalize this idea and we will see three of these frameworks: *Dynamic*, *Strongly Adaptive*, and *Tracking* regret.

#### 14.1 Dynamic Regret

Our first extension is to use multiple comparators, using the concept of dynamic regret, defined as

$$\text{D-Regret}(\boldsymbol{u}_1,\ldots,\boldsymbol{u}_T) := \sum_{t=1}^T \ell_t(\boldsymbol{x}_t) - \sum_{t=1}^T \ell_t(\boldsymbol{u}_t),$$

where  $u_1, \ldots, u_T \in \mathcal{V}$  and  $\mathcal{V} \subseteq \mathbb{R}^d$  is the feasible set. For additional clarity, we will also refer to the standard notion of regret as the *static regret*.

Is it possible to obtain sublinear dynamic regret? We already know that in the case that  $u_1 = \cdots = u_T$  it is possible, because we recover the standard regret case. On the other hand, it should be intuitive that the problem becomes more and more difficult the more the sequence of  $u_t$  changes over time. There are various ways to quantity this complexity and a common one is the *path-length*  $P^{\phi}: \mathcal{V}^T \to \mathbb{R}$  defined as

$$P^{\phi}(u_1,\ldots,u_T) := \sum_{t=2}^{T} \phi(u_t - u_{t-1}),$$

where  $\phi: \mathcal{V} \to \mathbb{R}$  is a function that measures the shift from  $u_{t-1}$  to  $u_t$ . In particular, we will instantiate  $\phi$  to be a norm. In the following, we will show how to design online algorithm whose dynamic regret depends on the path length in the case that the feasible set is bounded.

#### 14.1.1 Dynamic Regret of Online Mirror Descent

It turns out that some online learning algorithm already satisfies a dynamic regret without any additional change. For Online Mirror Descent (OMD), we can state the following theorem.

**Theorem 14.1.** Let  $B_{\psi}$  the Bregman divergence w.r.t.  $\psi : \mathcal{X} \to \mathbb{R}$  and assume  $\psi$  to be closed and  $\lambda$ -strongly convex with respect to  $\|\cdot\|$  in  $\mathcal{V} \cap \operatorname{int} \mathcal{X}$ . Let  $\mathcal{V} \subseteq \mathcal{X}$  a non-empty closed convex set. Assume that  $\mathbf{x}_t \in \operatorname{int} X$  for  $t = 1, \ldots, T$ .

Then,  $\forall \mathbf{u}_1, \dots, \mathbf{u}_T \in \mathcal{V}$ , OMD with constant learning rate  $\eta$  satisfies

$$D-Regret(\boldsymbol{u}_1,\ldots,\boldsymbol{u}_T) \leq \frac{B_{\psi}(\boldsymbol{u}_{T+1};\boldsymbol{x}_1) + QP^{\|\cdot\|}(\boldsymbol{u}_1,\ldots,\boldsymbol{u}_T)}{\eta} + \frac{\eta}{2\lambda} \sum_{t=1}^T \|\boldsymbol{g}_t\|_{\star}^2 - \frac{B_{\psi}(\boldsymbol{u}_{T+1};\boldsymbol{x}_{T+1})}{\eta},$$

where  $Q = \max_t \|\nabla \psi(\boldsymbol{x}_t) - \nabla \psi(\boldsymbol{x}_1)\|_{\star}$ .

*Proof.* From the one-step inequality for OMD with competitor  $u_t$ , we have

$$\eta(\ell_{t}(\boldsymbol{x}_{t}) - \ell_{t}(\boldsymbol{u}_{t})) \leq B_{\psi}(\boldsymbol{u}_{t}; \boldsymbol{x}_{t}) - B_{\psi}(\boldsymbol{u}_{t}; \boldsymbol{x}_{t+1}) + \frac{\eta^{2}}{2\lambda} \|\boldsymbol{g}_{t}\|_{\star}^{2} 
= B_{\psi}(\boldsymbol{u}_{t}; \boldsymbol{x}_{t}) - B_{\psi}(\boldsymbol{u}_{t+1}; \boldsymbol{x}_{t+1}) + B_{\psi}(\boldsymbol{u}_{t+1}; \boldsymbol{x}_{t+1}) - B_{\psi}(\boldsymbol{u}_{t}; \boldsymbol{x}_{t+1}) + \frac{\eta_{t}^{2}}{2\lambda} \|\boldsymbol{g}_{t}\|_{\star}^{2}.$$

Dividing by  $\eta$  and summing over time, we have

$$\begin{split} \sum_{t=1}^{T} (\ell_{t}(\boldsymbol{x}_{t}) - \ell_{t}(\boldsymbol{u}_{t})) &\leq \sum_{t=1}^{T} \frac{B_{\psi}(\boldsymbol{u}_{t}; \boldsymbol{x}_{t}) - B_{\psi}(\boldsymbol{u}_{t+1}; \boldsymbol{x}_{t+1})}{\eta} + \sum_{t=1}^{T} \frac{B_{\psi}(\boldsymbol{u}_{t+1}; \boldsymbol{x}_{t+1}) - B_{\psi}(\boldsymbol{u}_{t}; \boldsymbol{x}_{t+1})}{\eta} + \sum_{t=1}^{T} \frac{\eta}{2\lambda} \|\boldsymbol{g}_{t}\|_{\star}^{2} \\ &= \frac{B_{\psi}(\boldsymbol{u}_{1}; \boldsymbol{x}_{1}) - B_{\psi}(\boldsymbol{u}_{T+1}; \boldsymbol{x}_{T+1})}{\eta} + \sum_{t=1}^{T} \frac{B_{\psi}(\boldsymbol{u}_{t+1}; \boldsymbol{x}_{t+1}) - B_{\psi}(\boldsymbol{u}_{t}; \boldsymbol{x}_{t+1})}{\eta} + \frac{\eta}{2\lambda} \sum_{t=1}^{T} \|\boldsymbol{g}_{t}\|_{\star}^{2} \,. \end{split}$$

Now observe that

$$B_{\psi}(\boldsymbol{u}_{t+1}; \boldsymbol{x}_{t+1}) - B_{\psi}(\boldsymbol{u}_{t}; \boldsymbol{x}_{t+1})$$

$$= \psi(\boldsymbol{u}_{t+1}) - \psi(\boldsymbol{x}_{t+1}) - \langle \nabla \psi(\boldsymbol{x}_{t+1}), \boldsymbol{u}_{t+1} - \boldsymbol{x}_{t+1} \rangle - \psi(\boldsymbol{u}_{t}) + \psi(\boldsymbol{x}_{t+1}) + \langle \nabla \psi(\boldsymbol{x}_{t+1}), \boldsymbol{u}_{t} - \boldsymbol{x}_{t+1} \rangle$$

$$= \psi(\boldsymbol{u}_{t+1}) - \psi(\boldsymbol{u}_{t}) + \langle \nabla \psi(\boldsymbol{x}_{1}), \boldsymbol{u}_{t} - \boldsymbol{u}_{t+1} \rangle + \langle \nabla \psi(\boldsymbol{x}_{t+1}) - \nabla \psi(\boldsymbol{x}_{1}), \boldsymbol{u}_{t} - \boldsymbol{u}_{t+1} \rangle.$$

Hence, we have

$$\begin{split} \sum_{t=1}^{T} (B_{\psi}(\boldsymbol{u}_{t+1}; \boldsymbol{x}_{t+1}) - B_{\psi}(\boldsymbol{u}_{t}; \boldsymbol{x}_{t+1})) \\ &= \psi(\boldsymbol{u}_{T+1}) - \psi(\boldsymbol{u}_{1}) + \langle \nabla \psi(\boldsymbol{x}_{1}), \boldsymbol{u}_{1} - \boldsymbol{u}_{T+1} \rangle + \sum_{t=1}^{T} \langle \nabla \psi(\boldsymbol{x}_{t+1}) - \nabla \psi(\boldsymbol{x}_{1}), \boldsymbol{u}_{t} - \boldsymbol{u}_{t+1} \rangle \\ &= B_{\psi}(\boldsymbol{u}_{T+1}; \boldsymbol{x}_{1}) - B_{\psi}(\boldsymbol{u}_{1}; \boldsymbol{x}_{1}) + \sum_{t=1}^{T} \langle \nabla \psi(\boldsymbol{x}_{t+1}) - \nabla \psi(\boldsymbol{x}_{1}), \boldsymbol{u}_{t} - \boldsymbol{u}_{t+1} \rangle . \end{split}$$

Putting all together, we have

$$\text{D-Regret}(\boldsymbol{u}_{1},\ldots,\boldsymbol{u}_{T}) \leq \frac{B_{\psi}(\boldsymbol{u}_{T+1};\boldsymbol{x}_{1}) - B_{\psi}(\boldsymbol{u}_{T+1};\boldsymbol{x}_{T+1})}{\eta} + \frac{\eta}{2\lambda} \sum_{t=1}^{T} \|\boldsymbol{g}_{t}\|_{\star}^{2} + \frac{1}{\eta} \sum_{t=1}^{T} \langle \nabla \psi(\boldsymbol{x}_{t+1}) - \nabla \psi(\boldsymbol{x}_{1}), \boldsymbol{u}_{t} - \boldsymbol{u}_{t+1} \rangle.$$

Assuming that  $\|\nabla \psi(x_t) - \nabla \psi(x_1)\|_{\star} \leq Q$  and using the definition of dual norm, we have the stated bound.

Assuming  $\|g_t\|_{\star} \leq L$  and selecting the usual learning rate  $\eta = \frac{\alpha\sqrt{2\lambda}}{L\sqrt{T}}$ , we have

D-Regret
$$(\boldsymbol{u}_1,\ldots,\boldsymbol{u}_T) \leq \frac{\sqrt{2}L}{\sqrt{\lambda}} \left( \frac{B_{\psi}(\boldsymbol{u}_{T+1};\boldsymbol{x}_1) + QP^{\|\cdot\|}(\boldsymbol{u}_1,\ldots,\boldsymbol{u}_T)}{\alpha} + \alpha \right) \sqrt{T}$$
.

In words, we suffer an additional regret of

$$\sqrt{2}L\frac{QP^{\|\cdot\|}(\boldsymbol{u}_1,\ldots,\boldsymbol{u}_T)}{\alpha\sqrt{\lambda}}\sqrt{T}$$

compared to the static case, for any  $u_1, \ldots, u_T \in \mathcal{V}$ .

**Example 14.2.** Consider the case that the feasible is has diameter D with respect to the L2 norm, i.e.,  $D = \max_{\boldsymbol{x}, \boldsymbol{y} \in \mathcal{V}} \|\boldsymbol{x} - \boldsymbol{y}\|_2$ . Set  $\psi(\boldsymbol{x}) = \frac{1}{2} \|\boldsymbol{x}\|_2^2$  and assume the subgradients to satisfy  $\|\boldsymbol{g}_t\|_* \leq L$  for  $t = 1, \ldots, T$ . In this case, we have that Q = D and setting  $\eta = \frac{\alpha}{L\sqrt{T}}$  we have

D-Regret
$$(\boldsymbol{u}_1,\ldots,\boldsymbol{u}_T) \leq \frac{1}{2} \left( \frac{D^2 + 2D P^{\|\cdot\|}(\boldsymbol{u}_1,\ldots,\boldsymbol{u}_T)}{\alpha} + \alpha \right) L\sqrt{T}$$
.

This means that we get sublinear regret with respect to any sequence of competitors whose path length is  $o(\sqrt{T})$  as T goes to infinity.

Could we obtain a better regret guarantee? We could set the learning rate to  $\eta = \frac{\sqrt{2\lambda}\sqrt{B_{\psi}(u_{T+1};x_1) + QP^{\|\cdot\|}(u_1,...,u_T)}}{L\sqrt{T}}$  to obtain the dynamic regret

D-Regret
$$(\boldsymbol{u}_1,\ldots,\boldsymbol{u}_T) \leq \frac{\sqrt{2}}{\sqrt{\lambda}} L \sqrt{(B_{\psi}(\boldsymbol{u}_{T+1};\boldsymbol{x}_1) + QP^{\|\cdot\|}(\boldsymbol{u}_1,\ldots,\boldsymbol{u}_T))} \sqrt{T}$$
.

This would give us a sublinear regret with respect to any sequence of competitors whose path length is o(T) as T goes to infinity, that is a larger set than the one in the example. However, assuming the knowledge of the exact value of  $P^{\|\cdot\|}$  is unreasonable because it violates the assumption of the adversarial nature of the problem. This mirrors the problem of tuning the learning rate with the knowledge of  $\|x_1 - u\|$  in online gradient descent. Fortunately, there is a solution and we will see it in the next section.

#### 14.1.2 ADER: Optimal Dependency on the Path Length for Online Subgradient Descent

In the previous section, we saw that the algorithm needs to know the path length of the competitors in order to tune its learning rate. Here, we show how to construct an online learning algorithm that achieves the same guarantees up to polylogarithmic terms. For simplicity, we will consider the Euclidean case, but it is easy to extend it to the Bregman case. Moreover, we assume the losses to be *L*-Lipschitz w.r.t. the L2 norm.

We will use a classic online learning method: running a number of projected Online Gradient Descent (OGD) algorithms with different learning rates in parallel and using an Exponentiated Algorithm to learn online the best combination of their iterates. In this way, we will show that the cumulative loss of the resulting algorithm is close to the cumulative loss of the best learning rate, that in turn will give us the right dependency on the path length.

Consider a feasible set V with bounded L2 diameter D and assume of the losses  $\ell_t$  to be L-Lipschitz. Using projected OGD with learning rate  $\eta$ , we obtain the following regret upper bound

D-Regret
$$(\boldsymbol{u}_1,\ldots,\boldsymbol{u}_T) \leq \frac{1}{2} \left( \frac{D^2 + 2DP^{\|\cdot\|_2}(\boldsymbol{u}_1,\ldots,\boldsymbol{u}_T)}{\eta} + \eta L^2 \right) \sqrt{T}, \ \forall \boldsymbol{u}_1,\ldots,\boldsymbol{u}_T \in \mathcal{V}.$$

Using the fact that  $P^{\|\cdot\|_2}(\boldsymbol{u}_1,\ldots,\boldsymbol{u}_T) \leq DT$ , the optimal choice of  $\eta^\star = \frac{\sqrt{D^2 + 2D\,P^{\|\cdot\|_2}(\boldsymbol{u}_1,\ldots,\boldsymbol{u}_T)}}{L\sqrt{T}}$  satisfies

$$\frac{D}{L\sqrt{T}} \le \eta^* \le \frac{D\sqrt{1+2T}}{L\sqrt{T}} \ .$$

So, consider a grid of  $N=1+\lceil \ln_2\sqrt{4+8T}\rceil$  learning rates  $\eta^{(i)}=\frac{D2^{i-1}}{L\sqrt{T}}, i=1,\ldots,N$ , so that  $\eta^{(1)}=\frac{D}{L\sqrt{T}}$  and  $\eta^{(N)}\geq 2\frac{D\sqrt{1+2T}}{L\sqrt{T}}$ . This implies that there exists  $i^\star$  such that

$$\eta^{(i^{\star})} \leq \eta^{\star} \leq 2\eta^{(i^{\star})}$$
.

#### Algorithm 14.1 Adaptive learning for Dynamic EnviRonment (ADER)

**Require:** Non-empty, closed, and convex feasible set  $\mathcal{V} \subseteq \mathbb{R}^d$ , number of iterations T, diameter of the feasible set  $D < \infty$ , Lipschitz constant L, initial point  $x_1 \in \mathcal{V}$ 

```
1: Set N = 1 + \lceil \ln_2(\sqrt{4 + 8T}) \rceil

2: Set \eta^{(i)} = \frac{D2^{i-1}}{L\sqrt{T}}, i = 1, ..., N

3: Set \beta = \frac{\sqrt{2 \ln N}}{LD\sqrt{T}}
 4: \boldsymbol{p}_1 = [1/N, \dots, 1/N] \in \mathbb{R}^N

5: \boldsymbol{x}_1^{(i)} = \boldsymbol{x}_1, i = 1, \dots, N

6: for t = 1 to T do

7: Output \boldsymbol{x}_t = \sum_{i=1}^N p_{t,i} \boldsymbol{x}_t^{(i)} and pay \ell_t(\boldsymbol{x}_t)

8: Receive \boldsymbol{g}_t \in \partial \ell_t(\boldsymbol{x}_t)
                   Update each OGD: x_{t+1}^{(i)} = \Pi_{\mathcal{V}}(x_t - \eta^{(i)}g_t), i = 1, ..., N
                   Update EG: p_{t+1,i} \propto p_{t,i} \exp\left(-\beta \langle \boldsymbol{g}_t, \boldsymbol{x}_t^{(i)} \rangle\right), i = 1, \dots, N
11: end for
```

To combine the OGD algorithms with different learning rates, we use the EG algorithm where the OGD algorithms are our experts. Construct the loss vector for EG as  $z_t = [\ell_t(x_t^{(1)}), \dots, \ell_t(x_t^{(N)})]^{\top}$ . The EG algorithm is invariant to additive constants to the coordinates of the loss vector (see Exercise 6.10), hence we can consider as if it were running on the losses  $\ell_t(x^{(i)}) - \ell_t(x_1)$  that makes them bounded in absolute value by DL. Hence, using a uniform prior and learning rate  $\beta = \frac{\sqrt{2 \ln N}}{LD\sqrt{T}}$ , we obtain the regret

$$\sum_{t=1}^{T} \langle \boldsymbol{p}_t, \boldsymbol{z}_t \rangle - \min_i \sum_{t=1}^{T} z_{t,i} \leq \sqrt{2} L \, D \sqrt{T \ln N} \leq \sqrt{2} L \, D \sqrt{T \ln \left(2 + \ln_2 \sqrt{4 + 8T}\right)} \; .$$

Now observe that by Jensen's inequality and the convexity of  $\ell_t$ , we have

$$\langle oldsymbol{p}_t, oldsymbol{z}_t 
angle = \sum_{i=1}^N p_{t,i} \ell_t(oldsymbol{x}_t^{(i)}) \geq \ell_t \left(\sum_{i=1}^N p_{t,i} oldsymbol{x}_t^{(i)}
ight) = \ell_t(oldsymbol{x}_t) \;.$$

This motivates the choice of using a convex combination of the predictions of the OGD algorithms. Moreover, we have  $\min_i \sum_{t=1}^T z_{t,i} = \min_i \sum_{t=1}^T \ell_t(\boldsymbol{x}_t^{(i)})$ . From the regret of OGD and the choice of  $\eta^{(i)}$ , we have

$$\min_{i} \sum_{t=1}^{T} \ell_{t}(\boldsymbol{x}_{t}^{(i)}) \leq \sum_{t=1}^{T} \ell_{t}(\boldsymbol{x}_{t}^{(i^{\star})}) \leq \sum_{t=1}^{T} \ell_{t}(\boldsymbol{u}_{t}) + \frac{3}{2}L\sqrt{T(D^{2} + 2DP^{\|\cdot\|_{2}}(\boldsymbol{u}_{1}, \dots, \boldsymbol{u}_{T}))}, \ \forall \boldsymbol{u}_{1}, \dots, \boldsymbol{u}_{T} \in \mathcal{V}.$$

Putting all together, we have

$$\begin{aligned} & \text{D-Regret}(\boldsymbol{u}_1, \dots, \boldsymbol{u}_T) \\ &= \sum_{t=1}^T (\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u}_t)) \\ &= \sum_{t=1}^T (\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{x}_t^{(i^*)})) + \sum_{t=1}^T (\ell_t(\boldsymbol{x}_t^{(i^*)}) - \ell_t(\boldsymbol{u}_t)) \\ &\leq \sqrt{2}LD\sqrt{T \ln\left(2 + \ln_2\sqrt{4 + 8T}\right)} + \frac{3}{2}L\sqrt{T(D^2 + 2DP^{\|\cdot\|_2}(\boldsymbol{u}_1, \dots, \boldsymbol{u}_T))}, \ \forall \boldsymbol{u}_1, \dots, \boldsymbol{u}_T \in \mathcal{V}. \end{aligned}$$

We are still not completely done: This construction above queries  $N = \mathcal{O}(\ln T)$  subgradients in each step, so now we show how to reduce it to only one subgradient per iteration. This is easily achieved: It is enough to run the construction on the linear surrogate losses  $\tilde{\ell}_t(\boldsymbol{x}) = \langle \boldsymbol{g}_t, \boldsymbol{x} \rangle$ , where  $\boldsymbol{g}_t \in \partial \ell_t(\boldsymbol{x}_t)$ . The advantage is that  $\partial \tilde{\ell}_t(\boldsymbol{x}) = \{\boldsymbol{g}_t\}$  for all  $\boldsymbol{x}$ , hence all the OGD algorithms receive the same subgradient! Once again, we have that  $|\tilde{\ell}_t(\boldsymbol{x}_t) - \tilde{\ell}_t(\boldsymbol{x}_1)| \leq LD$ . Moreover, we have

$$\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u}_t) \le \langle \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{u}_t \rangle = \tilde{\ell}_t(\boldsymbol{x}_t) - \tilde{\ell}_t(\boldsymbol{u}_t), \ \forall \boldsymbol{u}_t \in \mathcal{V}.$$

Hence, a dynamic regret guarantee on  $\tilde{\ell}_t$  immediately translates to a dynamic regret guarantee on  $\ell_t$ . The resulting algorithm is called Adaptive learning for Dynamic EnviRonment (ADER) and it is in Algorithm 14.1. Formally, we have the following theorem.

**Theorem 14.3.** Let  $V \subseteq \mathbb{R}^d$  be a non-empty closed convex set with bounded diameter with respect to the L2 norm equal to D. Assume  $\ell_t : V \to \mathbb{R}$  to be convex functions subdifferentiable in V and L-Lipschitz with respect to the L2 norm. Then,  $\forall u_1, \ldots, u_T \in V$ , Algorithm 14.1 satisfies

D-Regret
$$(u_1, ..., u_T) \le \frac{3}{2} L \sqrt{T(D^2 + 2DP^{\|\cdot\|_2}(u_1, ..., u_T))} + \sqrt{2} L D \sqrt{T \ln(2 + \ln_2 \sqrt{4 + 8T})}$$
.

Note that while we query only one subgradient per round, the computational complexity of ADER per round is still  $\mathcal{O}(\ln T)$  when T goes to infinity. This is due to the fact that in each round we need to update  $\mathcal{O}(\ln T)$  different OGD algorithms.

**Remark 14.4.** One might wonder if the same strategy can get the performance of the parameter-free algorithms. Unfortunately, here we critically used the fact that the losses of EG are bounded. If we consider unbounded domains, as in the parameter-free algorithms, this is not true anymore.

#### 14.2 Strongly Adaptive Regret

We now introduce the concept of strongly adaptive regret: For any  $u \in \mathcal{V}$ , we define

$$\mathrm{SA\text{-}Regret}_{T,\tau}(\boldsymbol{u}) := \max_{[s,s+\tau-1]\subseteq[1,2,\ldots,T]} \ \sum_{t=s}^{s+\tau-1} \ell_t(\boldsymbol{x}_t) - \sum_{t=s}^{s+\tau-1} \ell_t(\boldsymbol{u}) \ .$$

This definition captures the fact that we want the performance of the algorithm to be good on any interval of length  $\tau$ . We will say that the algorithm is *strongly adaptive* if the additional price we pay with respect to learning on any specific interval of length  $\tau$  is at most polylogarithmic in T.

**Remark 14.5.** One might be tempted to remove the dependency on  $\tau$  and consider

$$\max_{\tau} \; \mathrm{SA\text{-}Regret}_{T,\tau}(\boldsymbol{u}) \; .$$

This notion is known as adaptive regret. However, it is clear that  $\max_{\tau} \operatorname{SA-Regret}_{T,\tau}(u) = \Omega(\sqrt{T})$  for bounded domains and Lipschitz losses (from the lower bound in Chapter 5), that is meaningless for intervals of size  $\mathcal{O}(\sqrt{T})$ . Hence, the adaptive regret does not allow us to reason on the performance of the algorithm on small intervals.

In the next section, we show how to obtain strongly adaptive algorithms, using once again a combination of online learning algorithms.

#### 14.2.1 CBCE: A Meta Algorithm for Strongly Adaptive Regret

We will introduce now the Coin Betting for Changing Environment (CBCE) algorithm, see Algorithm 14.3. We use T different OCO algorithms, each one starting at a different time step, and we combine them with a sleeping-experts algorithm over a countably infinite number of experts. In particular,  $x_t^{(s)}$  is the output at time t of the OCO algorithm started at time t, while t is the convex combination of t using the probability distribution produced by the sleeping expert algorithm. Using the sleeping expert algorithm in Section 10.7, immediately gives the following theorem.

#### Algorithm 14.2 Coin Betting for Changing Environment (CBCE)

**Require:** Non-empty, closed, and convex feasible set  $\mathcal{V} \subseteq \mathbb{R}^d$ , black-box algorithm  $\mathcal{B}$ , sleeping expert algorithm  $\mathcal{M}$ 

- 1: for t = 1 to T do
- Get  $p_t$  from  $\mathcal{M}$  such that  $p_{t,i} \neq 0$ , for  $i = 1, \ldots, t$
- Get  $\boldsymbol{x}_t^{(i)}$  from the copy i of  $\mathcal{B}$ , for  $i=1,\ldots,t$ Output  $\boldsymbol{x}_t = \sum_{i=1}^t p_{t,i} \boldsymbol{x}_t^{(i)}$  and pay  $\ell_t(\boldsymbol{x}_t)$
- Receive  $\boldsymbol{g}_t \in \overline{\partial} \ell_t(\boldsymbol{x}_t)$

- Pass  $\tilde{\ell}_t(\boldsymbol{x}) = \langle \boldsymbol{g}_t, \boldsymbol{x} \rangle$  to the copy i of  $\mathcal{B}$ , for  $i = 1, \ldots, t$ Let  $\boldsymbol{v}_t = [\langle \boldsymbol{g}_t, \boldsymbol{x}_t^{(1)} \rangle, \ldots \langle \boldsymbol{g}_t, \boldsymbol{x}_t^{(t)} \rangle, 0, 0, \ldots] \in \mathbb{R}^{\infty}$ Pass the loss  $\ell_t^{\text{sleeping}}(\boldsymbol{x}) = \langle \boldsymbol{v}_t, \boldsymbol{x} \rangle$  to the sleeping expert algorithm
- 9: end for

**Theorem 14.6.** Let  $V \subseteq \mathbb{R}^d$  a non-empty closed convex set. Let M the algorithm in Section 10.7, where  $\epsilon_i = \frac{1}{i(i+1)}$ for  $i=1,2,\ldots$ , and  $\mathcal{B}$  an online learning algorithm that satisfies  $\operatorname{Regret}_t(\boldsymbol{u}) \leq R_t(\boldsymbol{u})$  for all  $t \in \mathbb{N}$ , where  $R_t: \mathcal{V} \to \mathbb{R}$ . Let  $I = [s, s + \tau - 1] \subset [1, 2, ...]$ . Then, Algorithm 14.2 satisfies

$$\operatorname{Regret}_I(\boldsymbol{u}) := \sum_{t \in I} (\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) \le R_\tau(\boldsymbol{u}) + \mathcal{O}\left(\sqrt{\tau \ln(s^2 \tau)}\right), \ \forall \boldsymbol{u} \in \mathcal{V}.$$

*Proof.* Like in the case of ADER, a simple implementation of this algorithm would require to query t values of the function  $\ell_t$  at time t. However, we run the algorithm on the linearized losses  $\langle q_t, \cdot \rangle$ , where  $q_t \in \ell_t(x_t)$ , so that the subgradient is only asked once. Hence, we upper bound the regret using the linearized losses:

$$\sum_{t=s}^{s+ au-1} (\ell_t(oldsymbol{x}_t) - \ell_t(oldsymbol{u})) \leq \sum_{t=s}^{s+ au-1} \langle oldsymbol{g}_t, oldsymbol{x}_t - oldsymbol{u} 
angle = \sum_{t=s}^{s+ au-1} ( ilde{\ell}_t(oldsymbol{x}_t) - ilde{\ell}_t(oldsymbol{u})) \ .$$

Next, we decompose the regret in the contributes of  $\mathcal{B}$  and  $\mathcal{M}$  as

$$\sum_{t=c}^{s+\tau-1} (\tilde{\ell}_t(\boldsymbol{x}_t) - \tilde{\ell}_t(\boldsymbol{u})) = \sum_{t=c}^{s+\tau-1} (\tilde{\ell}_t(\boldsymbol{x}_t) - \tilde{\ell}_t(\boldsymbol{x}_t^{(s)})) + \sum_{t=c}^{s+\tau-1} (\tilde{\ell}_t(\boldsymbol{x}_t^{(s)}) - \tilde{\ell}_t(\boldsymbol{u})) .$$

The first sum can be written as

$$\sum_{t=s}^{s+\tau-1} (\tilde{\ell}_t(\boldsymbol{x}_t) - \tilde{\ell}_t(\boldsymbol{x}_t^{(s)})) = \text{Regret}_{s+\tau-1}^{\text{sleeping}}(\boldsymbol{e}_s),$$

because the s-th copy of the algorithm  $\mathcal{B}$  has been active only on rounds s to s+q-1. With the choice of  $\epsilon_i = \frac{1}{i(i+1)}$ , the sleeping expert algorithm in Section 10.7 achieves a sleeping regret against the s-th expert of  $\mathcal{O}(\sqrt{\tau \ln(s^2\tau)})$ , because the expert s has been active for  $\tau$  rounds. For the second sum, we simply have  $R_{\tau}(u)$  because the s-th copy of algorithm  $\mathcal{B}$  was started on round s.

Hence, assuming that  $R_{\tau}(\mathbf{u}) = \mathcal{O}(\sqrt{\tau})$ , the CBCE algorithm is strongly adaptive because the regret on any interval of length  $\tau$  depends on  $\sqrt{\tau}$  and only logarithmically on T.

However, while we ask only one subgradient per round, the computational complexity of CBCE in round t is proportional to t, because we have to update t OCO algorithms. So, in the next section, we consider an efficient variant of the CBCE algorithm, whose update is proportional to  $\ln t$ , with the same strongly adaptive regret guarantee.

#### 14.2.2 **Efficient Version of CBCE**

The previous algorithm has the disadvantage of requiring to start a new copy of algorithm  $\mathcal{B}$  in each iteration. Instead, here we will see how to reduce the number of copies to the logarithm of the number of rounds, using geometric coverings.

#### Algorithm 14.3 Efficient Coin Betting for Changing Environment

**Require:** Non-empty, closed, and convex feasible set  $\mathcal{V} \subseteq \mathbb{R}^d$ , black-box algorithm  $\mathcal{B}$ , sleeping expert algorithm  $\mathcal{M}$ 

- 1: **for** t = 1 **to** T **do**
- 2: Get  $p_t$  from the sleeping expert algorithm  $\mathcal{M}$ , such that  $p_{t,J} \neq 0$  only for  $J \in ACTIVE(t)$
- 3: Get  $x_t^{(J)}$  from the copy of  $\mathcal{B}$  for  $J \in ACTIVE(t)$
- 4: Output  $m{x}_t = \sum_{J \in ACTIVE(t)} p_{t,J} m{x}_t^{(J)}$  and pay  $\ell_t(m{x}_t)$
- 5: Receive  $g_t \in \partial \ell_t(x_t)$
- 6: Pass  $\tilde{\ell}_t(x) = \langle g_t, x \rangle$  to the copy of  $\mathcal{B}$  for  $J \in ACTIVE(t)$
- 7: Let  $\mathbf{v}_{t,J} = \begin{cases} \langle \mathbf{g}_t, \mathbf{x}_t^{(J)} \rangle, & J \in ACTIVE(t) \\ 0, & \text{otherwise} \end{cases}$
- 8: Pass the loss  $\ell_t^{
  m sleeping}(m{x}) = \langle m{v}_t, m{x} 
  angle$  to the sleeping expert algorithm  ${\cal M}$
- 9: end for

Figure 14.1: Geometric covering intervals. Each interval is denoted by [ ].

For  $k = 0, 1, 2, \ldots$ , define the intervals

$$\mathcal{I}_k := \{ [i2^k, (i+1)2^k - 1] : i \in \mathbb{N} \}.$$

That is, each  $\mathcal{I}_k$  is a partition of  $\mathbb{N}\setminus\{1,2,\ldots,2^k-1\}$  to consecutive intervals of length  $2^k$ . Also, define

$$\mathcal{I} := \cup_{k=0,1,2,\dots} \mathcal{I}_k$$

and

$$ACTIVE(t) := \{ J \in \mathcal{I} : t \in J \},$$

the set of the "active" intervals at time t, that is, the intervals that contain t. By the definition of  $\mathcal{I}_k$ , for every  $t \leq 2^k - 1$  we have that no interval in  $\mathcal{I}_k$  contains t, while for every  $t \geq 2^k$  we have that a single interval in  $\mathcal{I}_k$  contains t. Therefore,  $|ACTIVE(t)| = \lfloor \log_2 t \rfloor + 1$ . We will run a copy of an OCO algorithm for each active interval, this means that we have a number of algorithms at each time step t that is logarithmic in t. Given an interval J of  $\mathbb{N}$ , we will also use the definition of  $\mathcal{I}|_J$ 

$$\mathcal{I}|_J := \{ I \in \mathcal{I} : I \subseteq J \},\$$

to denote the set of the intervals in  $\mathcal{I}$  that contains a J.

The next lemma allows to decompose the regret over any interval using the regret over intervals in  $\mathcal{I}$ .

**Lemma 14.7.** Let  $J = [q, s] \subseteq \mathbb{N}$  be an arbitrary interval. Then, the interval J can be partitioned into two finite sequences of disjoint and consecutive intervals, denoted  $(J_{-k}, \ldots, J_0) \subseteq \mathcal{I}|_J$  and  $(J_1, J_2, \ldots, J_p) \subseteq \mathcal{I}|_J$ , such that

- $|J_{-i}|/|J_{-i+1}| < 1/2, \forall i > 1$ .
- $|J_i|/|J_{i-1}| \le 1/2, \forall i \ge 2.$

*Proof.* The intuition of the proof is the following one: First, we choose the interval  $J_0$  to be the biggest leftmost one in  $\mathcal{I}|_J$ . Then, we show that the others are selected so that they decrease in size to the left, while on the right  $J_1$  can have the same size of  $J_0$  and the others will decrease in size.

Denote the size of  $J_i$  by  $b_i$  for  $i=-k,\ldots,0,\ldots,p$  and let  $b_0=\max\{|J'|:J'\in\mathcal{I}|_J\}$  be the maximal size of any interval  $J'\in\mathcal{I}$  that is contained in J. Among all of these intervals, let  $J_0$  be the leftmost interval, i.e., we define

$$q_0 := \operatorname{argmin}\{q' : [q', q' + b_0 - 1] \in \mathcal{I}|_J\},\$$
 $s_0 := q_0 + b_0 - 1,$ 
 $J_0 := [q_0, s_0].$ 

Starting from  $q_0 - 1$ , we now define a sequence of intervals (in a reversed order), denoted  $(J_{-1}, \ldots, J_{-k})$  to cover the interval  $[1, q_0 - 1]$ , as follows:

$$[q_{-1}, s_{-1}] := J_{-1} := \underset{J' = [q', s'] \in \mathcal{I}|_{[q, q_0 - 1]} : s' = q_0 - 1}{\operatorname{argmax}} |J'|$$

$$\vdots$$

$$[q_{-i}, s_{-i}] := J_{-i} := \underset{J' = [q', s'] \in \mathcal{I}|_{[q, q_{i+1} - 1]} : s' = q_{-i+1} - 1}{\operatorname{argmax}} |J'|$$

$$\vdots$$

Clearly, this sequence is finite and the left endpoint of the leftmost interval,  $J_{-k}$ , is q. Denote the size of  $J_{-i}$  by  $b_{-i}$ . We next prove that for every  $i \geq 1$ ,  $b_{-i}/b_{-i+1} \leq 1/2$ . Given that the intervals are powers of 2, it suffices to show that  $b_{-i} < b_{-i+1}$  for every  $i \geq 1$ . We use induction. The base case follows from the fact that  $b_0 > q_0$ , otherwise it would contradict the maximality of  $b_0$  and the fact that  $J_0$  is the leftmost biggest interval. We next assume that the claim holds for every  $i \in \{1, \ldots, n-1\}$  and prove for n. Assume by contradiction that  $b_{-n} \geq b_{-n+1}$ . Consider the interval  $\hat{J}_{-n+1}$  which is obtained by extending  $J_{-n+1}$  to its left by an additional size of  $b_{-n+1}$ , that is,  $\hat{J}_{-n+1} := [q_{-n+1} - b_{-n+1}, q_{-n+1} - 1] \cup J_{-n+1}$ . Hence,  $\hat{J}_{-n+1}$  is an interval of size  $2b_{-n+1}$  and it is contained in J. According to the induction hypothesis,  $|\hat{J}_{-n+1}| = 2b_{-n+1} = 2^j b_{-n+2}$  for some  $j \leq 0$ . Given that  $\hat{J}_{-n+1}$  is adjacent to the interval  $J_{-n+2}$  and its size is  $2^j |J_{-n+2}|$  for some  $j \leq 0$ , from the definition of  $\mathcal{I}$ , we have that  $\hat{J}_{-n+1} \in \mathcal{I}|_J$ , contradicting the maximality of  $J_{-n+1}$ .

Similarly, we define a sequence of disjoint and consecutive intervals, denoted  $(J_1, \ldots, J_p)$  that covers  $[s_0 + 1, s]$ .

$$[q_1, s_1] := J_1 := \underset{J' = [q', s'] \in \mathcal{I}|_{[s_0 + 1, s]} : q' = s_0 + 1}{\operatorname{argmax}} |J'|$$

$$\vdots$$

$$[q_i, s_i] := J_i := \underset{J' = [q', s'] \in \mathcal{I}|_{[s_{i-1} + 1, s]} : q' = s_{i-1} + 1}{\operatorname{argmax}} |J'|$$

$$\vdots$$

Clearly, this sequence is finite and the right endpoint of the rightmost interval,  $J_p$ , is s. Denote the size of  $J_i$  by  $b_i$ . We next prove that for every  $i \ge 2$ ,  $b_i/b_{i-1} \le 1/2$  that is equivalent to  $b_i < b_{i-1}$ .

We prove it again by induction. We assume that  $b_i/b_{i-1} \in \{2^j: j \leq 0\}$  for every  $i \in \{1,\dots,n-1\}$  and prove that  $b_n < b_{n-1}$  for  $n \geq 2$ . For the base case, from the definition of  $b_0$  we have that  $b_1 \leq b_0$ . Now, assume by contradiction that  $b_n \geq b_{n-1}$ . Then, we can consider the interval  $\hat{J}_{n-1}$  which is obtained by extending  $J_{n-1}$  to its right by an additional size of  $b_{n-1}$ . It follows that  $\hat{J}_{n-1}$  is an interval of size  $2b_{n-1}$  and it is contained in J. According to the induction hypothesis,  $|\hat{J}_{n-1}| = 2b_{n-1} = 2^j b_{n-2}$  for some  $j \leq 1$ . We need to consider the following two cases:

- Case  $j \leq 0$  (i.e.,  $b_{n-1}/b_{n-2} \leq 1/2$ ). Then,  $\hat{J}_{n-1}$  is consecutive to  $J_{n-2} \in \mathcal{I}$  and its size is  $2^j |J_{n-2}|$ , hence  $\hat{J}_{n-1} \in \mathcal{I}|_J$ , contradicting the maximality of  $J_{n-1}$ .
- Case j=1 (i.e.,  $b_{n-1}=b_{n-2}$ ). Then,  $|\hat{J}_{n-1}|=2b_{n-2}$  and this contradicts the maximality of  $J_{n-2}$ .

As an example of the above Lemma, consider the interval J=[1,30] that is partitioned in the intervals  $J_{-3}=[1]$ ,  $J_{-2}=[2,3], J_{-1}=[4,7], J_0=[8,15], J_1=[16,23], J_2=[24,27], J_3=[28,29], J_4=[30].$ 

We will use an expert algorithm over a countable number of experts, hence we also have a prior  $\pi$  over the infinite-dimensional simplex  $\Delta^{\infty} := \{ \boldsymbol{x} \in \mathbb{R}^{\infty} : x_i \geq 0, \sum_{i=1}^{\infty} x_i = 1 \}$ . For simplicity of notation, we denote by  $\pi_I$  the elements of  $\pi \in \Delta^{\infty}$  associated with the interval I.

**Theorem 14.8.** Let  $V \subseteq \mathbb{R}^d$  a non-empty closed convex set. Let M be the algorithm in Section 10.7, where the copy associated to the interval  $J = [i_1, i_2] \in \mathcal{I}$  has the parameter  $\epsilon_J$  defined recursively as

$$\epsilon_J = \begin{cases} \frac{1}{i_1(i_1+1)(\lfloor \log_2 i_1 \rfloor + 1)}, & J \in \mathcal{I}_0 \\ \sum_{I \in \mathcal{I}_0 \mid_J} \epsilon_I, & J \in \mathcal{I}_k, k \geq 1 \end{cases}.$$

Let  $\mathcal{B}$  be an online learning algorithm that satisfies  $\operatorname{Regret}_t(\boldsymbol{u}) \leq ct^{\alpha}$  for all  $\boldsymbol{u} \in \mathcal{V}$  and  $t \in \mathbb{N}$ , where  $\alpha \in (0,1)$ . Let  $I = [s, s + \tau - 1] \subset [1, 2, \ldots]$ . Then, Algorithm 14.3 satisfies

$$\operatorname{Regret}_I(\boldsymbol{u}) := \sum_{t \in I} (\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) \le 2 \frac{2^{\alpha} - (4\tau^2)^{-\alpha}}{2^{\alpha} - 1} c\tau^{\alpha} + \mathcal{O}(\sqrt{\tau \ln(s + \tau)}), \ \forall \boldsymbol{u} \in \mathcal{V}.$$

*Proof.* First of all, we upper bound the regret over the interval I with the one over linearized losses:

$$\sum_{t \in I} (\ell_t(\boldsymbol{x}_t) - \ell_t(\boldsymbol{u})) \leq \sum_{t \in I} \langle \boldsymbol{g}_t, \boldsymbol{x}_t - \boldsymbol{u} \rangle = \sum_{t \in I} (\tilde{\ell}_t(\boldsymbol{x}_t) - \tilde{\ell}_t(\boldsymbol{u})),$$

where  $\tilde{\ell}_t(\boldsymbol{x}) = \langle \boldsymbol{g}_t, \boldsymbol{x} \rangle$ .

Now, suppose we denote by  $x_t^{(J)}$  the decision from the black-box run  $\mathcal{B}_J$  associated with the interval J at time t and by  $x_t$  the combined decision of the meta algorithm at time t. Since the complete algorithm is a combination of a meta algorithm  $\mathcal{M}$  and several black-box algorithms  $\mathcal{B}$ , its regret depends on both  $\mathcal{M}$  and  $\mathcal{B}$ . We now decompose the two sources of regret additively through the geometric covering.

Let  $\mathcal{J} = \bigcup_{i=-a}^{b} J_i$  be the partition of I obtained from Lemma 14.7. Then, the regret on I can be decomposed as follows:

$$\operatorname{Regret}_{I}(\boldsymbol{u}) = \sum_{t \in I} \left( \tilde{\ell}_{t}(\boldsymbol{x}_{t}) - \ell_{t}(\boldsymbol{u}) \right)$$

$$\leq \sum_{t \in I} \left( \tilde{\ell}_{t}(\boldsymbol{x}_{t}) - \tilde{\ell}_{t}(\boldsymbol{u}) \right)$$

$$= \sum_{i=-a}^{b} \sum_{t \in J_{i}} \left( \tilde{\ell}_{t}(\boldsymbol{x}_{t}) - \tilde{\ell}_{t}(\boldsymbol{x}_{t}^{(J_{i})}) + \tilde{\ell}_{t}(\boldsymbol{x}_{t}^{(J_{i})}) - \tilde{\ell}_{t}(\boldsymbol{u}) \right)$$

$$= \sum_{i=-a}^{b} \sum_{t \in J_{i}} \left( \tilde{\ell}_{t}(\boldsymbol{x}_{t}) - \tilde{\ell}_{t}(\boldsymbol{x}_{t}^{(J_{i})}) \right) + \sum_{i=-a}^{b} \sum_{t \in J_{i}} \left( \tilde{\ell}_{t}(\boldsymbol{x}_{t}^{(J_{i})}) - \tilde{\ell}_{t}(\boldsymbol{u}) \right) . \tag{14.1}$$

$$\text{meta regret on } J_{i} \text{ black-box regret on } J_{i}$$

The black-box regret on  $J_i \in \mathcal{J}$  is exactly the regret of the black-box algorithm on  $|J_i|$  rounds, since the black-box run  $\mathcal{B}_{J_i}$  was started at the beginning of the interval  $J_i$ . In particular, we have

$$\sum_{i=-a}^{b} \sum_{t \in J_i} (\tilde{\ell}_t(\boldsymbol{x}^{(J_i)}) - \tilde{\ell}_t(\boldsymbol{u})) = \sum_{i=-a}^{b} \sum_{t \in J_i} \langle \boldsymbol{g}_t, \boldsymbol{x}^{(J_i)} - \boldsymbol{u} \rangle \le \sum_{i=-a}^{b} c |J_i|^{\alpha} \le 2c \sum_{k=0}^{a+b+1} (2^{-k}|I|)^{\alpha}$$
$$= 2c|I|^{\alpha} \frac{2^{\alpha} - 2^{-\alpha(a+b+1)}}{2^{\alpha} - 1} \le 2c|I|^{\alpha} \frac{2^{\alpha} - (4|I|^2)^{-\alpha}}{2^{\alpha} - 1},$$

where the second inequality is due to Lemma 14.7 and in the last one we used that the number of geometric cover intervals is less than  $2(\lfloor \log_2 |I| \rfloor + 1)$  (again from Lemma 14.7) and  $2^{-2(\lfloor \log_2 |I| \rfloor + 1)} \ge \frac{1}{4|I|^2}$ .

Now, we show that  $\mathcal{M}$  has low regret on interval  $J \in \mathcal{J}$ , considering separately the regret on  $J_i$  for  $i \in [-a, 0]$  and  $i \in [1, b]$ . The critical observation is that

$$\sum_{i=-a}^{0} \sum_{t \in J_i} (\tilde{\ell}_t(\boldsymbol{x}_t) - \tilde{\ell}_t(\boldsymbol{x}^{(J_i)})) = \sum_{i=-a}^{0} \operatorname{Regret}_{s+\tau-1}^{\text{sleeping}}(\boldsymbol{e}_{J_i}),$$

where the equality holds because the expert associated to  $J_i$  is active only for the rounds in  $J_i$ . Using the guarantee on the sleeping regret in Section 10.7, we have

$$\begin{split} \sum_{i=-a}^{0} \mathrm{Regret}_{s+\tau-1}^{\mathrm{sleeping}}(e_{J_{i}}) &\leq \sum_{i=-a}^{0} \mathcal{O}\left(\sqrt{|J_{i}| \ln \frac{|J_{i}|}{\epsilon_{J_{i}}}}\right) \leq \sum_{i=-a}^{0} \mathcal{O}\left(\sqrt{2^{i}\tau \ln(s+\tau)}\right) \leq \sum_{k=0}^{\infty} \mathcal{O}\left(\sqrt{2^{-k}\tau \ln(s+\tau)}\right) \\ &= \mathcal{O}\left(\sqrt{\tau \ln(s+\tau)}\right), \end{split}$$

where the second inequality is due to Lemma 14.7. Analogously, we have

$$\sum_{i=1}^b \operatorname{Regret}_{s+ au-1}^{ ext{sleeping}}(oldsymbol{e}_{J_i}) = \mathcal{O}(\sqrt{ au \ln(s+ au)}) \ .$$

Putting all together, we have the stated bound.

**Remark 14.9.** Observe that the limit for  $\alpha \to 0$  of the first term of the upper bound of the regret is  $2c \log_2(8\tau^2)$ . However, the second term is always of the order of  $\sqrt{\tau}$ .

From the above theorem, it is immediate to get a guarantee on the strongly adaptive regret by observing that

$$\mathrm{SA\text{-}Regret}_{T,\tau}(\boldsymbol{u}) = \max_{|I| = \tau} \ \mathrm{Regret}_I(\boldsymbol{u}) \:.$$

#### 14.3 Tracking Regret

There is yet another way to measure the ability of an online algorithm to adapt to changes in the behaviour of the adversarial losses: the **Tracking Regret**. For  $m \in \{0, ..., T\}$ , define

$$\text{T-Regret}_T^m(\boldsymbol{u}_1,\ldots,\boldsymbol{u}_T) := \text{D-Regret}_T(\boldsymbol{u}_1,\ldots,\boldsymbol{u}_T),$$

where the sequence  $u_1, \ldots, u_T \in \mathcal{V}$  changes at most m times. More formally, there exists a partition of  $\{1, 2, \ldots, T\}$  formed by  $(\mathcal{I}_i)_{i=0}^m$  and  $\tilde{u}_0, \ldots, \tilde{u}_m \in \mathcal{V}$  such that for all t in each  $\mathcal{I}_i$  the  $u_t = \tilde{u}_i$ .

The tracking regret can be upper bounded both in terms of dynamic regret and strongly adaptive regret. Indeed, if we assume the diameter of D of  $\mathcal V$  to be bounded with respect to some norm, i.e.,  $D = \max_{u,v \in \mathcal V} \|u - v\| < \infty$ , then for a sequence  $u_1, \ldots, u_T \in \mathcal V$  that changes at most m times we have

$$P_T^{\|\cdot\|}(\boldsymbol{u}_1,\ldots,\boldsymbol{u}_T) \leq mD$$
.

Hence, any algorithm with a dynamic regret guarantee that depends on  $P_T^{\|\cdot\|}$  can also be used to obtain a tracking regret guarantee.

For example, we can consider the following algorithm.

**Example 14.10.** Consider the setting of learning with expert advice. In this setting, the tracking regret makes more sense because we are typically interested in competitors that are corners of the simplex.

To tackle this problem, we will use OMD with the entropic regularizer over the truncated simplex  $\mathcal{V} = \{ \boldsymbol{x} \in \mathbb{R}^d : x_i \geq \alpha/d, \sum_{i=1}^d x_i = 1 \}$ , where  $\alpha$  is a parameter that will be decided in the following. Hence, we have  $x_{t,i} \geq \frac{\alpha}{d}$  and  $(\nabla \psi(\boldsymbol{x}))_i = 1 + \ln x_i$ . Hence, in the dynamic case we have

$$Q = \max_{t} \|\nabla \psi(\boldsymbol{x}_{t}) - \nabla \psi(\boldsymbol{x}_{1})\|_{\infty} = \max_{t} \|\ln \boldsymbol{x}_{t} - \ln \boldsymbol{x}_{1}\|_{\infty} \leq \ln \frac{d}{\alpha},$$

where the logarithm is taken element-wise.

Given that we want to consider  $u_t$  in the simplex rather than in the truncated simplex, we have

$$\langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \boldsymbol{u}_{t} \rangle = \left\langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \left( (1 - \alpha) \boldsymbol{u}_{t} + \frac{1 \alpha}{d} \right) \right\rangle + \left\langle \boldsymbol{g}_{t}, \alpha \left( \frac{1}{d} - \boldsymbol{u}_{t} \right) \right\rangle$$

$$\leq \left\langle \boldsymbol{g}_{t}, \boldsymbol{x}_{t} - \left( (1 - \alpha) \boldsymbol{u}_{t} + \frac{1 \alpha}{d} \right) \right\rangle + 2\alpha \|\boldsymbol{g}_{t}\|_{\infty}.$$

Denoting  $\tilde{\boldsymbol{u}}_t = (1 - \alpha)\boldsymbol{u}_t + \frac{1\alpha}{d} \in \mathcal{V}$ , the bound will depend on

$$\sum_{t=2}^{T} \|\tilde{\boldsymbol{u}}_{t} - \tilde{\boldsymbol{u}}_{t-1}\|_{1} = (1 - \alpha) \sum_{t=2}^{T} \|\boldsymbol{u}_{t} - \boldsymbol{u}_{t-1}\|_{1}.$$

Hence, using a uniform prior, we have the tracking regret bound

$$\text{T-Regret}_T^m(\boldsymbol{u}_1,\ldots,\boldsymbol{u}_T) \leq \frac{\ln d + (1-\alpha)P^{\|\cdot\|_1}(\boldsymbol{u}_1,\ldots,\boldsymbol{u}_T)\ln\frac{d}{\alpha}}{\eta} + \left(\frac{\eta}{2} + 2\alpha\right)\sum_{t=1}^T \|\boldsymbol{g}_t\|_{\infty}^2.$$

Given that the sequence  $u_1, \ldots, u_T$  changes at most m times, this means that  $P^{\|\cdot\|_1}(u_1, \ldots, u_T) \leq m$ . So, we have

T-Regret<sub>T</sub><sup>m</sup>
$$(\boldsymbol{u}_1, \dots, \boldsymbol{u}_T) \leq \frac{\ln d + m \ln \frac{d}{\alpha}}{\eta} + \frac{\eta T}{2} + 2\alpha T$$
.

Choosing 
$$\eta = \sqrt{\frac{2(\ln d + m \ln \frac{d}{\alpha})}{T}}$$
 and  $\alpha = \sqrt{\frac{m}{2T}}$ , we have

$$\text{T-Regret}_T^m(\boldsymbol{u}_1,\ldots,\boldsymbol{u}_T) \leq \sqrt{2T} \left( \sqrt{m \frac{\ln d}{m} + m \ln \frac{d\sqrt{2T}}{\sqrt{m}}} + \sqrt{m} \right) = \sqrt{2T} \left( \sqrt{(1+m) \ln d + \frac{m}{2} \ln \frac{2T}{m}} + \sqrt{m} \right).$$

We can also use strongly adaptive regret guarantee to control the tracking regret, as detailed in the next Theorem.

**Theorem 14.11.** Consider an algorithm that guarantees SA-Regret<sub>T</sub>  $\tau(u) \le c\tau^{\alpha}$  for  $\alpha \in (0,1)$ . Then,

T-Regret<sub>T</sub><sup>m</sup>
$$(\boldsymbol{u}_1,\ldots,\boldsymbol{u}_T) \leq c(m+1)^{\alpha}T^{1-\alpha}, \forall m \in \{0,\ldots,T-1\}.$$

Proof.

$$\text{T-Regret}_{T}^{m}(\boldsymbol{u}_{1},\ldots,\boldsymbol{u}_{T}) = \sum_{i=0}^{m} \sum_{t \in \mathcal{I}_{i}} (\ell_{t}(\boldsymbol{x}_{t}) - \ell_{t}(\tilde{\boldsymbol{u}}_{i})) \leq \sum_{i=0}^{m} c|\mathcal{I}_{i}|^{\alpha} \leq c \left(\sum_{i=0}^{m} 1^{\frac{1}{1-\alpha}}\right)^{1-\alpha} \left(\sum_{i=0}^{m} |\mathcal{I}_{i}|\right)^{\alpha}$$
$$= c(m+1)^{1-\alpha} T^{\alpha},$$

where in the first inequality we used the assumption on the strongly adaptive regret and in the last one we used Hölder's inequality.  $\Box$ 

#### 14.4 History Bits

Littlestone and Warmuth [1994] introduced the tracking regret in the learning with expert game, but upper bounding the number of mistakes, rather than the regret. The extension to arbitrary losses is in Herbster and Warmuth [1998]. Zinkevich [2003] is often erroneously thought to have introduced the dynamic regret, while it first appeared in Herbster and Warmuth [2001], with upper bounds that depend on the drift  $\sum_{t=2}^{T} \| \boldsymbol{u}_t - \boldsymbol{u}_{t-1} \|_p$ .

Theorem 14.1 is a generalization of Cesa-Bianchi and Lugosi [2006, Theorem 11.4] to arbitrary distance generating functions and considering Lipschitz losses. Also, following Jacobsen and Cutkosky [2022, Lemma 4], I have fixed the offset in the proof so that we do not have to assume that  $0 \in \mathcal{V}$ .

Zhang et al. [2018] designed the ADER algorithm and they also proved that it is optimal in bounded domains. The idea of combining online algorithms with different learning rates comes directly from the MetaGrad algorithm [van Erven and Koolen, 2016, van Erven et al., 2021] that also showed how to query a single gradient per round. In turn, MetaGrad is based builds on prior work on using a grid of learning rates in EG [Koolen et al., 2014]. By now, this is a well-known method that allows to solve essentially all problems of tuning learning rates in bounded domains, at least theoretically. One can also combine different learning rates in unbounded domains, with a multi-scale expert algorithm [Foster et al., 2017, Cutkosky and Orabona, 2018]. This method can be considered as a better "doubling trick" because it allows to track non-monotonic quantities at the price of a logarithmic computational overhead. It is worth also stressing that the general idea of combining the outputs of different online learning algorithms through another online learning algorithm is instead much older, and it goes back at least to Blum and Mansour [2005, 2007].

I described a slightly simpler version of ADER with a flat prior, see Exercise 14.1 for the original bound. I also removed the unnecessary assumption that  $0 \in \mathcal{V}$ . Recently, Zhao et al. [2020, 2024] improved the guarantees of ADER using optimistic algorithms, obtaining smaller bounds in easy environments.

The adaptive regret is defined in Hazan and Seshadhri [2007, 2009]. The strongly-adaptive regret was defined by Adamskiy et al. [2012, 2016] (still calling it "adaptive regret") and then reinvented in Daniely et al. [2015] (that coined the name). Note that the strongly-adaptive regret is usually defined for bounded domains, taking the maximum with respect  $u \in \mathcal{V}$ , instead I defined it more generally for any competitor in the feasible set. Lemma 14.7 is from Daniely et al. [2015] as well. The efficient version of the CBCE algorithm was proposed by Jun et al. [2017a,b] using a stronger version of the sleeping expert algorithm, still based on coin betting. Here, I simplified the sleeping expert algorithm for didactical reasons. CBCE improves over the guarantee in Daniely et al. [2015] by improving the logarithmic term. The idea of using linearized losses in CBCE to avoid querying more than one subgradients and the better behaviour of the first term in the bound when  $\alpha \to 0$  are new. The non-efficient version of CBCE is also new, but straightforward.

The algorithm in Example 14.10 is introduced in Herbster and Warmuth [2001] and generalized to arbitrary distance generating functions in Cesa-Bianchi et al. [2012]. Theorem 14.11 is from Daniely et al. [2015].

#### 14.5 Exercises

**Problem 14.1.** Change the prior in the EG algorithm to obtain a dependency of  $\ln \ln (1 + P^{\|\cdot\|_2}(\boldsymbol{u}_1, \dots, \boldsymbol{u}_T))$  instead of  $\ln \ln T$ . In this way, if the path length is zero, that is we are in the static case, the regret is  $\mathcal{O}(\sqrt{T})$  instead of  $\mathcal{O}(\sqrt{T} \ln \ln T)$ , when  $T \to \infty$ .

## Appendix A

## **More Convex Analysis**

#### A.1 Fundamental Theorem of Calculus

**Theorem A.1** ([Hiriart-Urruty and Lemaréchal, 2004, Theorem 2.3.4, page 179]). Let  $f: \mathbb{R}^d \to (-\infty, +\infty]$  be proper and convex. For  $x, y \in \text{int dom } f$  and  $t \in [0, 1]$ , define  $x_t = ty + (1 - t)x$ . Then, for any  $g_t \in \partial f(x_t)$ , we have

$$f(\boldsymbol{y}) - f(\boldsymbol{x}) = \int_0^1 \langle \boldsymbol{g}_t, \boldsymbol{y} - \boldsymbol{x} \rangle \, \mathrm{d}t \ .$$

#### **A.2** Strongly Convex Functions

**Lemma A.2.** Let  $f : \mathbb{R}^d \to (-\infty, +\infty]$  be proper and  $\mu$ -strongly convex with respect to a norm  $\|\cdot\|$  over a convex set  $\mathcal{V} \subseteq \operatorname{dom} \partial f$ , where  $\mu > 0$ . Then, for all  $x, y \in \mathcal{V}$ ,  $g \in \partial f(y)$ , and  $g' \in \partial f(x)$ , we have

$$f(\boldsymbol{x}) - f(\boldsymbol{y}) \le \langle \boldsymbol{g}, \boldsymbol{x} - \boldsymbol{y} \rangle + \frac{1}{2\mu} \|\boldsymbol{g} - \boldsymbol{g}'\|_{\star}^2.$$

*Proof.* Define  $\phi(z) = f(z) - \langle g, z \rangle$ . Observe that  $0 \in \partial \phi(y)$ , hence y is a minimizer of  $\phi(z)$  by Theorem 6.29. Also, note that  $g' - g \in \partial \phi(x)$ . Hence, by Lemma 4.2, we can write

$$\begin{split} \phi(\boldsymbol{y}) &= \min_{\boldsymbol{z} \in \text{dom } \phi} \ \phi(\boldsymbol{z}) \\ &\geq \min_{\boldsymbol{z} \in \text{dom } \phi} \ \left( \phi(\boldsymbol{x}) + \langle \boldsymbol{g}' - \boldsymbol{g}, \boldsymbol{z} - \boldsymbol{x} \rangle + \frac{\mu}{2} \|\boldsymbol{z} - \boldsymbol{x}\|^2 \right) \\ &\geq \min_{\boldsymbol{z} \in \mathbb{R}^d} \ \left( \phi(\boldsymbol{x}) + \langle \boldsymbol{g}' - \boldsymbol{g}, \boldsymbol{z} - \boldsymbol{x} \rangle + \frac{\mu}{2} \|\boldsymbol{z} - \boldsymbol{x}\|^2 \right) \\ &= \phi(\boldsymbol{x}) - \frac{1}{2\mu} \|\boldsymbol{g}' - \boldsymbol{g}\|_{\star}^2, \end{split}$$

where the last step comes from the conjugate function of squared norms, see Example 6.21.

**Corollary A.3.** Let  $f : \mathbb{R}^d \to (-\infty, +\infty]$  closed, proper, and  $\mu$ -strongly convex with respect to a norm  $\|\cdot\|$  over its domain. Let  $\mathbf{x}^* = \operatorname{argmin}_{\mathbf{x}} f(\mathbf{x})$ . Then, for all  $\mathbf{x} \in \operatorname{dom} \partial f$ , and  $\mathbf{g} \in \partial f(\mathbf{x})$ , we have

$$f(x) - f(x^*) \le \frac{1}{2\mu} ||g||_*^2$$
.

## Appendix B

# **Probabilistic Inequalities**

**Theorem B.1** (Khintchine's inequality). Let  $\{\epsilon_n\}_{n=1}^N$  be i.i.d. random variables with  $\mathbb{P}\{\epsilon_n=1\}=\mathbb{P}\{\epsilon_n=-1\}=\frac{1}{2}$  for  $n=1,\ldots,N$ , i.e., a sequence with Rademacher distribution. Let  $0< p<\infty$  and let  $x_1,\ldots,x_N\in\mathbb{C}$ . Then, we have

$$A_p \left( \sum_{n=1}^N |x_n|^2 \right)^{1/2} \le \left( \mathbb{E} \left| \sum_{n=1}^N \epsilon_n x_n \right|^p \right)^{1/p} \le B_p \left( \sum_{n=1}^N |x_n|^2 \right)^{1/2},$$

where

$$A_p = \begin{cases} 2^{1/2 - 1/p} & 0 
$$B_p = \begin{cases} 1 & 0$$$$

where  $p_0 \approx 1.847$  and  $\Gamma$  is the Gamma function.

The constants in the above theorem are due to Haagerup [1981].

### **Appendix C**

## The Lambert Function and Its Applications

The Lambert function  $W: \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$  is defined by the equality

$$x = W(x) \exp(W(x)) \qquad \text{for } x \ge 0.$$
 (C.1)

Hence, from the definition we have that  $\exp(W(x)/2) = \sqrt{\frac{x}{W(x)}}.$ 

We have the following properties of the Lambert function, stated without proof.

**Theorem C.1.** The Lambert function satisfies the following properties:

• 
$$\lim_{x \to +\infty} \frac{W(x)}{\ln x} = 1$$

**Theorem C.2** ([Hoorfar and Hassani, 2008, Theorem 2.3]).

$$W(x) \le \ln \frac{x+C}{1+\ln(C)}, \quad \forall x > -\frac{1}{e}, \ C > \frac{1}{e}.$$

The following lemma provides upper and lower bounds on W(x).

**Theorem C.3** ([Orabona and Pál, 2016, Lemma 17]). The Lambert function W(x) satisfies

$$0.6321 \ln(x+1) \le W(x) \le \ln(x+1), \ \forall x \ge 0.$$

*Proof.* The inequalities are satisfied for x = 0, hence we in the following we assume x > 0. We first prove the lower bound. From (C.1) we have

$$W(x) = \ln\left(\frac{x}{W(x)}\right) . (C.2)$$

From this equality, using the elementary inequality  $\ln(x) \leq \frac{a}{a} x^{\frac{1}{a}}$  for any a > 0, we get

$$W(x) \leq \frac{1}{a \, e} \left(\frac{x}{W(x)}\right)^a \ \forall a > 0,$$

that is

$$W(x) \le \left(\frac{1}{ae}\right)^{\frac{1}{1+a}} x^{\frac{a}{1+a}} \quad \forall a > 0.$$
 (C.3)

Using (C.3) in (C.2), we have

$$W(x) \ge \ln\left(\frac{x}{\left(\frac{1}{a\,e}\right)^{\frac{1}{1+a}}\,x^{\frac{a}{1+a}}}\right) = \frac{1}{1+a}\ln\left(a\,e\,x\right) \;\;\forall a > 0 \;.$$

Consider now the function  $g(x) = \frac{x}{x+1} - \frac{b}{\ln(1+b)(b+1)} \ln(x+1)$  defined in [0,b] where b is a positive number that will be decided in the following. This function has a maximum in  $x^* = (1+\frac{1}{b}) \ln(1+b) - 1$ , the derivative is positive in  $[0,x^*]$  and negative in  $[x^*,b]$ . Hence the minimum is in x=0 and in x=b, where it is equal to 0. Using the property just proved on g, setting  $a=\frac{1}{x}$ , we have

$$W(x) \ge \frac{x}{x+1} \ge \frac{b}{\ln(1+b)(b+1)} \ln(x+1) \ \forall x \le b.$$

For x > b, setting  $a = \frac{x+1}{ex}$ , we have

$$W(x) \ge \frac{e x}{(e+1)x+1} \ln(x+1) \ge \frac{e b}{(e+1)b+1} \ln(x+1)$$
 (C.4)

Hence, we set b such that

$$\frac{e\,b}{(e+1)b+1} = \frac{b}{\ln(1+b)(b+1)}$$

Numerically, b = 1.71825..., so

$$W(x) \ge 0.6321 \ln(x+1)$$
.

For the upper bound, we use Theorem C.2 and set C = 1.

**Theorem C.4.** Let a, b > 0. Then, the Fenchel conjugate of  $f(x) = b \exp(x^2/(2a))$  is

$$f^{\star}(\theta) = \sqrt{a}|\theta|\sqrt{W(a\theta^2/b^2)} - b\exp\left(\frac{W(a\theta^2/b^2)}{2}\right) = \sqrt{a}|\theta|\left(\sqrt{W(a\theta^2/b^2)} - \frac{1}{\sqrt{W(a\theta^2/b^2)}}\right).$$

Moreover,

$$\sqrt{a}|\theta|\left(\sqrt{0.6321\ln(a\theta^2/b^2+1)}-1\right)-b \le f^\star(\theta) \le \sqrt{a}|\theta|\sqrt{\ln(a\theta^2/b^2+1)}-b\;.$$

Proof. First, observe that

$$\max_{x} \theta x - b \exp(x^{2}/(2a)) = \max_{y} b \left( \frac{\sqrt{a\theta}}{b} y - \exp(y^{2}/2) \right).$$

Also, by the definition of Lambert function, we have

$$\underset{u}{\operatorname{argmax}} \ uy - \exp(y^2/2) = \operatorname{sign}(u)\sqrt{W(y^2)},$$

where  $\mathrm{sign}(u)=0$  for u=0. Hence,  $\mathrm{argmax}_x \ \theta x - b \exp(x^2/(2a)) = \mathrm{sign}(\theta) \sqrt{a} \sqrt{W(a\theta^2/b^2)}$ . So,

$$\begin{split} \max_x \; \theta x - b \exp(x^2/(2a)) &= \max_y \; b \left( \frac{\sqrt{a\theta}}{b} y - \exp(y^2/2) \right) \\ &= \sqrt{a} |\theta| \sqrt{W(a\theta^2/b^2)} - b \exp\left( \frac{W(a\theta^2/b^2)}{2} \right) \\ &= \sqrt{a} |\theta| \sqrt{W(a\theta^2/b^2)} - b \sqrt{\frac{a\theta^2/b^2}{W(a\theta^2/b^2)}} \\ &= \sqrt{a} |\theta| \left( \sqrt{W(a\theta^2/b^2)} - \frac{1}{\sqrt{W(a\theta^2/b^2)}} \right) \; . \end{split}$$

The upper bound is obtained through Theorem C.3 and upper bounding  $-b \exp\left(\frac{W(a\theta^2/b^2)}{2}\right)$  with -b. For the lower bound, we use again Theorem C.3 and observe that

$$-b \exp\left(\frac{W(a\theta^2/b^2)}{2}\right) \ge -b \exp\left(\frac{1}{2}\ln\left(a\theta^2/b^2+1\right)\right) = -b\sqrt{a\theta^2/b^2+1} = -\sqrt{a\theta^2+b^2} \ge -\sqrt{a}|\theta| - b. \quad \Box$$

## **Appendix D**

# Lower Bound for the Tail of the Binomial Distribution

First, we prove a novel handy result for the sum of binomial coefficients.

**Lemma D.1.** Let  $n \ge 1$  integer and  $n/2 \le k \le n$  integer. Define  $\phi(k,n) = \frac{1}{2}\sqrt{4k^2 - 4kn + (n+2)^2} - k - n/2 - 1$ . Then,  $\sum_{i=k}^{n} \binom{n}{i} \ge \binom{n}{k} \frac{k}{2k + \phi(k,n)}$ . Moreover,  $\phi(k,n)$  is non-increasing in the first argument.

*Proof.* First of all, observe that  $\phi(k,n)$  is non-increasing in the first argument. Indeed, the first derivative is

$$\frac{2k-n}{\sqrt{4k^2-4kn+(n+2)^2}}-1=\frac{2k-n-\sqrt{4k^2-4kn+(n+2)^2}}{\sqrt{4k^2-4kn+(n+2)^2}}\leq \frac{2k-n-\sqrt{4k^2-4kn+n^2}}{\sqrt{4k^2-4kn+(n+2)^2}}=0\;.$$

We will prove the statement by induction. The base case is easy:  $\sum_{i=n}^{n} \binom{n}{i} = 1 = \binom{n}{n} \frac{n}{2n + \phi(n,n)}$ . So, now assume that  $\sum_{i=k+1}^{n} \binom{n}{i} \ge \binom{n}{k+1} \frac{k+1}{2(k+1) + \phi(k+1,n)}$ . We have that

$$\sum_{i=k}^{n} \binom{n}{i} = \sum_{i=k+1}^{n} \binom{n}{i} + \binom{n}{k} \ge \binom{n}{k+1} \frac{k+1}{2(k+1) + \phi(k+1,n)} + \binom{n}{k}$$

$$= \binom{n}{k} \left( \frac{n-k}{k+1} \frac{k+1}{2k+2 + \phi(k+1,n)} + 1 \right) = \binom{n}{k} \left( \frac{n-k}{2k+2 + \phi(k+1,n)} + 1 \right)$$

$$\ge \binom{n}{k} \left( \frac{n-k}{2k+2 + \phi(k,n)} + 1 \right) = \binom{n}{k} \frac{k}{2k + \phi(k,n)},$$

where the last equality is due to the definition of  $\phi(k, n)$ .

**Remark D.2.** Note that this lower bound gives us  $\sum_{i=n/2+q}^{n} {n \choose i} \ge {n \choose n/2+q} \frac{n/2+q}{q+\sqrt{q^2+n+1}-1}$ . Hence, it is tight in q=n/2 and in q=0 is

$$\sum_{i=n/2}^{n} \binom{n}{i} \ge \binom{n}{n/2} \frac{n/2}{\sqrt{n+1}-1} \ge \binom{n}{n/2} \frac{n/2}{\sqrt{n}} = \binom{n}{n/2} \frac{\sqrt{n}}{2},$$

that is  $\frac{\sqrt{n}}{2}$  better than the trivial lower bound  $\sum_{i=n/2}^{n} {n \choose i} \geq {n \choose n/2}$ .

We denote the KL divergence between two Bernoulli distributions with parameters p and q as

$$D(p||q) = p \ln \left(\frac{p}{q}\right) + (1-p) \ln \left(\frac{1-p}{1-q}\right).$$

We can now state the bound on the tail of the Binomial distribution.

**Lemma D.3** (Bound on Binomial Tail). Let  $n \ge 1$  even and  $0 \le q \le n/2 - 1$  integer. Then,  $B_n \sim B(n, \frac{1}{2})$  satisfies

$$\mathbb{P}\left\{B_n \ge \frac{n}{2} + q\right\} \ge \frac{1}{3} \frac{1}{2q + \sqrt{n}} \sqrt{n \frac{n/2 + q}{n/2 - q}} \exp\left(-n \cdot D\left(\frac{1}{2} + \frac{q}{n} \left\|\frac{1}{2}\right)\right)$$
$$\ge \frac{1}{3} \frac{1}{\frac{2q}{\sqrt{n}} + 1} \exp\left(-n \cdot D\left(\frac{1}{2} + \frac{q}{n} \left\|\frac{1}{2}\right)\right).$$

*Note that the second upper bound also holds in* q = n/2.

Proof. By definition, we have

$$\mathbb{P}\left\{B_n \ge \frac{n}{2} + q\right\} = 2^{-n} \sum_{i=n/2+q}^{n} \binom{n}{i}.$$

From Lemma D.1, we have

$$\sum_{i=n/2+q}^{n} \binom{n}{i} \ge \binom{n}{n/2+q} \frac{n/2+q}{n+2q+\phi(n/2+q,n)} \ge \binom{n}{n/2+q} \frac{n/2+q}{2q+\sqrt{n}} \ .$$

We bound the binomial coefficient  $\binom{n}{k}$  by using Stirling's formula for the factorial. In particular, we use the explicit upper and lower bounds due to Robbins [1955] valid for any  $n \ge 1$ ,

$$\sqrt{2\pi n} \left(\frac{n}{e}\right)^n < n! < \exp\left(\frac{1}{12}\right) \sqrt{2\pi n} \left(\frac{n}{e}\right)^n \ .$$

Hence, for any  $1 \le k \le n-1$ , we have

$$\binom{n}{k} = \frac{n!}{k!(n-k)!}$$

$$> \frac{\sqrt{2\pi n} \, n^n e^{-n}}{\sqrt{2\pi k} \, k^k e^{-k} e^{1/12} \cdot \sqrt{2\pi (n-k)} \, (n-k)^{n-k} e^{-(n-k)} e^{1/12}}$$

$$= \frac{1}{\exp\left(\frac{1}{6}\right) \sqrt{2\pi}} \left(\frac{n}{n-k}\right)^{n-k} \left(\frac{n}{k}\right)^k \sqrt{\frac{n}{k(n-k)}}$$

$$= \frac{1}{\exp\left(\frac{1}{6}\right) \sqrt{2\pi}} \, 2^n \exp\left(-n \cdot D\left(\frac{k}{n} \middle\| \frac{1}{2}\right)\right) \sqrt{\frac{n}{k(n-k)}},$$

where in the equality we used the definition of D(p||q). Hence, we have

$$\binom{n}{n/2+q} \ge \frac{1}{\exp\left(\frac{1}{6}\right)\sqrt{2\pi}} 2^n \exp\left(-n \cdot D\left(\frac{1}{2} + \frac{q}{n} \left\| \frac{1}{2}\right)\right) \sqrt{\frac{n}{(n/2+q)(n/2-q)}} \right).$$

Combining all the inequalities and using the fact that  $\sqrt{\frac{n/2+q}{n/2-q}} \ge 1$ , we get the stated bound.

For q=n/2, we verify the statement of the theorem by direct substitution. The left hand side is  $\mathbb{P}[B_n \geq n] = 2^{-n}$ . Since  $\exp\left(-n \cdot D(1\|\frac{1}{2})\right) = 2^{-n}$ , it's easy to see that the right hand side is smaller than  $2^{-n}$ .

### Appendix E

# **Topology Bits**

**Definition E.1** (Bounded Set). A non-empty subset V in a metric space X with metric  $d(\cdot, \cdot)$  is **bounded** if  $\sup_{x,y \in V} d(x,y) < \infty$ .

**Definition E.2** (Open and Closed Sets). A subset V of a metric space X is said to be **open** if it contains a ball centered on each of its points. A subset V of X is **closed** if its complement in X is **open**.

**Remark E.3.** A set can be open, closed, both, or neither. In particular, the empty set and the entire metric space are both closed and open. An example of a set that is neither is the set (0,1] on  $\mathbb{R}$ .

**Definition E.4** (Neighborhood). In a metric space  $\mathcal{X}$ , a set  $\mathcal{V}$  is a **neighbourhood** of a point  $\mathbf{x}$  if there exists an open ball with centre  $\mathbf{x}$  and radius r > 0 contained in  $\mathcal{V}$ .

**Definition E.5** (Interior point and Interior of a Set). A point x is an interior point of a set V if V is a neighborhood of x. The interior of a set V, denoted by int V, is the set of all interior points of V.

Note that int V is the largest open set contained in V.

**Definition E.6** (Boundary points and Boundary of a Set). A point x is a **boundary point** of V in a metric space X with metric  $d(\cdot, \cdot)$  if every neighborhood of x contains points of V as well as points not in V. The **boundary of** V, denoted by bdry V, is the set of all boundary points of V.

**Theorem E.7.** For any subset V of a Euclidean space, V is compact if and only if it is closed and bounded.

**Theorem E.8** (Weierstrass theorem for extended functions [Bauschke et al., 2003, Theorem 1.28]). Let  $\mathcal{X}$  a Hausdorff space, let  $f: \mathcal{X} \to [-\infty, +\infty]$  be lower semicontinuous, and let  $\mathcal{V}$  be a compact subset of  $\mathcal{X}$ . Suppose  $V \cap \text{dom } f \neq \{\}$ . Then, f achieves its infimum over  $\mathcal{V}$ .
